SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

NEW SERIES. VOLUME XIII.

JANUARY-JUNE, 1901.

NEW YORK
THE MACMILLAN COMPANY
1901

THE NEW ERA PRINTING COMPANY,
41 North Queen Street,
Lancaster, Pa.

CONTENTS AND INDEX.

N. S. VOL. XIII.—JANUARY TO JUNE, 1901.

The Names of Contributors are Printed in Small Capitals.

A., J. A., Mammals of S. Africa, W. L. Sclater, 105
ADAMS, F. A., George M. Dawson, 561
Agricultural Experiment Stations, 331
Agriculture, Dept. of, 257, 315 ; E. W. ALLEN, 572
ALLEN, E. W., U. S. Department of Agriculture, 572
American Association for the Advancement of Science, 37, 425, 705, 811, 875, 902, 961, 995
AMES, J. H., Henry Augustus Rowland, 681
AMI, H. M., Stratigraphical Note, 394 ; Geological Survey of Canada, D. B. Dowling, 424 ; Ottawa Naturalists' Club, 469 ; R. Society of Canada, 1015
Anatomists, Association of American, D. S. LAMB, 289
André, Ch., Traité d'astronomie stellaire, E. B. FROST, 618 ; G. C. COMSTOCK, 746
ANDREWS, W. C., Amer. Inst. Electr. Engineers, 655
ANGELL, J. R., Monaural Localization of Sound, 775
Antarctic Expedition, 836 ; E. B. POULTON, 890
Anthropological Society of Washington, W. HOUGH, 308, 391, 547, 665, 786
Anthropology, at Baltimore, F. RUSSELL, 139 ; and Psychology at the N. Y. Acad. of Sci., C. H. JUDD, 309, 468 ; R. S. WOODWORTH, 662, 864
Antiquities of Michigan, Survey of, 672
Arbacia Punctulata, H. L. OSBORN, 938
Astronomy, Physics and Chemistry, N. Y. Acad. of Sci., W. S. DAY, 148, 346, 469, 866
ATKINSON, G. F., The Embryo-sac, 530
Auriferous Deposit, O. H. HERSHEY, 869

B., C. F., Bird Book ; Woodpeckers, F. H. Eckstorm, 658
B., F. A., Christian Frederik Lütken, 540
Baconian Club, Univ. of Iowa, C. E. SEASHORE, 826
Bacteriologists, Amer. Soc. of, H. W. CONN, 321
Bacteriology, W. T. SEDGWICK, 121
BAILEY, E. H. S., Kans. Acad. of Sci., 217
Bailey, L. H., Botany, C. E. BESSEY, 859
BALDWIN, J. M., Sidgwick Memorial, 274
Ball, Sir R., Astronomy, F. W. VERY, 581
BANKS, N., Notes on Entomology, 668 ; Gli Insetti Nocivi, A. Lunardoni, 706
BARBOUR, E. H., Nebr. Ornithologists' Union, 216
Barracleugh, S. H., Steam-engine Problem, R. H. THURSTON, 619
BARTON, G. E., Arsenic Tests, 470
BARUS, C., Stroboscopic Phenomena, 128 ; Projection of Ripples by a Grating, 297 ; Particles in Saturated Emanation of Phosphorus, 501 ; Remarks on the Top, 852 ; Rotation of a Rigid Body, 914
BASKERVILLE, C., Elisha Mitchell Soc., 548, 666, 827
BATHER, F. A., Bibliographic Catch Title, 230
BAUER, L. A., Magnetic Observations, 746
BENSLEY, B. A., Australian Marsupialia, 431
Bergen, J. Y., Botany, C. E. BESSEY, 859
BESSEY, C. E., Botanical Notes, 193, 397, 472, 714, 832 ; Botanical Literature, 298, 859
Bibliographic Catch Title, E. L. MARK, 31 ; F. A. BATHER, 230
Bibliographicum Concilium, 633
Bibliography of Geodesy, J. H. GORE, 868
BIGELOW, F. H., U. S. Naval Observatory, 150 ; Cyclones, 589
Bigelow, F. H., Cloud Observations, R. DEC. WARD, 24
Biological, Society of Washington, F. A. LUCAS, 26, 189, 307, 392, 428, 506, 585, 711, 909 ; W. H. OSGOOD, 787 ; Laboratory, Marine, of Woods Holl, 433 ; C. O. WHITMAN, 538 ; Problems, Statistical, 673 ; Station, Univ. of Montana, 873 ; New Mexico, T. D. A. COCKERELL, 954 ; Lectures, Columbia Univ., J. H. McG., 1035
Biology, W. H. HOWELL, 49 ; Section, N. Y. Acad. of Sci., F. E. LLOYD, 71, 467 ; H. E. CRAMPTON, 272
BIRGE, E. A., H. F. NACHTRIEB, and F. SMITH, State Natural History Surveys, 563 ; Limnological Commission, C. H. EIGENMANN, C. A. KOFOID, G. C. WHIPPLE, and H. B. WARD, 897
BOAS, F., The Mind of Primitive Man, 281
BOGUE, E. E., A Simple Osmometer, 791
Bolas, T., Photography in Colors, R. W. W., 109
BOLTON, H. C. Physics and Faith, 241
Bolton, H. C., The Thermometer, J. L. H., 146 ; Bibliography of Chemistry, J. L. HOWE, 784
Botanical, Club, Torrey, E. S. BURGESS, 27, 347, 586, 788, 912 ; Notes, C. E. BESSEY, 193, 397, 472, 714, 832 ; Literature, C. E. BESSEY, 298
Botany, Option in, Standard College Entrance, W. F. GANONG, 611 ; in Japan, KRICHI MIYAKE, 734
Boveri, T., Die Centrosomen, E. B. WILSON, 264
Bowers, G. M., Report of U. S. Fish Commissioner, H. C. BUMPUS, 23 ; M. C. MARSH, 106
Boyer, J., Mathematics, G. B. HALSTED, 462
BRITTON, N. L., Precedence in Nomenclature, 588
BROOKS, A. H., Cassiterite in Alaska, 593
Brooks, Thomas Benton, B. WILLIS, 460
BROOMALL, C. M., Lunar Halo, 549
BROWN, B. H., Constant Cross-Section, 831
Brühl, J. W., Pflanzen-Alkaloide, H. KRAEMER, 821
BUCHNER, E. F., A. KIRSCHMAN, J. R. ANGELL, A. M. BLEILE, E. D. STARBUCK, Disclaimer No. 2, 667
Buffalo, Wood, O. J. KLOTZ, 233
Bufo Agua in the Bermudas, F. C. WAITE, 342
BUMPUS, H. C., Report of U. S. Fish Commissioner, G. M. Bowers, 23
BURGESS, E. S., Torrey Botanical Club, 27, 347, 586, 788, 912

C., T. D. A., Las Vegas Science Club, 191, 469, 711

CALL, R. E., The Date of Rafinesque's Death, 548
Campanus, C. S. PEIRCE, 809
CAMPBELL, W. W., Observations of Eros, 176
Carnegie's, Mr., Gift to Scottish Universities, 1032
Catalogue, International, of Scientific Literature, 76
CHAMBERLAIN, A. F., Seri Indians, W J McGee, 779
CHAPLIN, W. S., Washington University, 258
Chemical, Society, American, 576 ; A. C. HALE, 104 ; N. Y. Section, D. WOODMAN, 191, 393, 711, 948 ; Washington, W. H. KRUG, 149, 308 ; L. S. MUNSON, 507, 664, 824, 910 ; N. C. Section, C. B. WILLIAMS, 899 ; Laboratory, E. H. KEISER, 261 ; Industries, W. M. McMURTRIE, 441
Chemistry, Inorganic, Notes on, J. L. H., 33, 313, 349, 434, 627, 831, 993 ; Dignity of, H. W. WILEY, 721 ; in the Nineteenth Century, E. H. KEISER, 803
CHILD, C. D., Velocity of Ions, 830
CHILD, C. M., Zoological Club, University of Chicago, 73, 112, 1026
Chough, Alpine, P. S. SCLATER, 626 ; W. J. FOX, 713
CHURCH, J. P., Reservoirs, J. D. Schuyler, 738
CLARK, W. B., The State and Investigation, 81
CLARKE, F. W., Free Speech in Universities, 309
Classen, A., Chemie, H. P. TALBOT, 660
CLAYTON, H. H., Cyclones, 747
Clayton's Eclipse Cyclone, F. H. BIGELOW, 589
Clements, F. E., and R. Pound, Phytogeography of Nebraska, A. HOLLICK, 981
COCKERELL, T. D. A., Predetermined Evolution, 311; Insect Fauna of Human Excrement, L. O. Howard, 389 ; Penycuik Experiments, Telegony, Zebra Hybrids, J. C. Ewart, 423 ; Naiades, C. T. Simpson, 983 ; New Mexico Biological Station, 954 ; The Mongoose in Jamaica, 990
Cohnheim, O., Chemie der Eiweisskörper, L. B. MENDEL, 185
COLE, F. N., Amer. Mathematical Society, 102, 429
COMSTOCK, G. C., André's Astronomie Stellaire, 746

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

THE NAVAL OBSERVATORY REPORT.

THE first impression of our readers on glancing at the annual report of the Naval Observatory, of which the essential portions are reprinted in our columns, will be one of pleasure that the head of the Observatory has deemed it appropriate to review the conclusions of the board of visitors appointed by the Secretary of the Navy in 1899. But pleasure will be changed to disappointment at what the review omits. It maintains with an energy of expression quite unusual in an official paper that a majority of the board was hostile to the Observatory; that it failed to report on the main points submitted, and that the measures which it proposed are 'preposterous' and 'only ridiculous.' But not a word is said in reply to the destructive criticism of the management of the institution 'during almost the entire period of its existence,' which is one of the most important features of the report. Had these strictures been now heard of for the first time some reason might have been found for ignoring them. But they are little more than an echo of strictures emanating from or endorsed by Secretaries of the Navy, the National Academy of Sciences, at least one distinguished naval offi-

cer, and every eminent astronomer in the country who has ever expressed an opinion on the subject. Utterances by such authorities are surely worthy of being honored by a refutation. We wish to facilitate in every way the task of making the most effective refutation possible, and this we can best do by stating the substance of the criticisms as clearly and forcibly as we can, without implying any endorsement of them until we hear the other side.

The only rational object that the nation can have in supporting a great public observatory is the continuous making of those astronomical observations which require to be prosecuted on a uniform plan for long intervals of time, with a force larger than private observatories can ordinarily command, and with a persistence more long-continued than they can be expected to exhibit. The first requirement of all is a comprehensive plan of work, devised by the best authorities at the command of the nation, and based on the latest aspects of astronomical science. This plan should be pursued without change except as improvements are suggested by the advance of research. It should be dependent on the life or temporary opinions of no individual, and should have a form of public support which will secure adherence to it.

The criticism directed against the Observatory is that its published observations and reports show little or nothing of this kind, and that neither permanence of purpose nor unity of object can be discerned in them. Much that we find in the published volumes looks like a collection of individual works of every degree of ability from the highest to the lowest, which have the appearance of being initiated by the worker himself, abandoned when he deemed it best to do so, and only now and then controlled by the guidance of any higher authority. Even in the case of those observations in which continuity from year to year can be best traced, gaps and unexplained changes and omissions occur through the whole history of the Observatory, for most of which no explanation is found, and none can be readily imagined except the varying moods of the observers.

In these points the critics see no evidence of any permanent improvement in the work of the new establishment. The reports for the last eight or ten years show earnest efforts made by this and that astronomer to do this, that and the other, set forth the difficulties encountered in making these efforts, report the success reached in overcoming them, and describe the alterations necessary in instruments and arrangements. Sometimes an effort made one year seems to be continued into the next, and sometimes we hear nothing more of it. It would be tedious to enumerate all the enterprises which figure for a year or two in the annual reports, without any reason being assigned, and then disappear without any explanation. There seems to be as striking an absence of continuity from year to year as there ever was, the work with the prime vertical transit excepted.

It is not denied by the critics that able and industrious astronomers have, from time to time, been attached to the institution, that the qualifications of the working force are still excellent, and that much good

work has been done by it; but it is also claimed that, for the most part, this work could have been equally well or better done at universities and private institutions, and that it is mixed up with so much indifferent work that the separation of the two is difficult. It is also admitted that much of the work compares favorably with that done by professors and students at the various colleges and universities of the country. But the critics do not see why the government should establish a great institution and give men commissions in the navy to enable them to do work which professors and students are doing at universities and which is of no special naval use.

In framing a reply to this criticism we trust that several other points which invite adverse criticism will be cleared up to the pleasure of all. One is especially worthy of mention because we think, if anything can be said to correct the unfavorable impression which it makes, it ought to be said authoritatively and as speedily as possible. Among the important subjects of scientific observation and investigation to-day is terrestrial magnetism. The good policy of the observatory in entering upon a field already occupied by another bureau of the government may be open to question, but this is aside from the main point. One of the best-equipped magnetic observatories was established and, we believe, observations made for a year or two. We learn from recent reports that the observations were suspended and the department discontinued, because the action of the electric current from a trolley line in the neighborhood so disturbed the instruments as to deprive the results of all scientific value. Now, we hope the head of the establishment will explain how it happened that one of the finest magnetic observatories in existence was established 400 yards from a trolley line, when a simple computation of the effect of the electric current by a magnetic expert would have shown that its inductive effect would be destructive to the results, and, unless we are mistaken as to dates, after experience elsewhere had shown that the presence of such a line within a mile or even a mile and a half of a magnetic station was fatal to the usefulness of its work. All good wishers of the Observatory would be glad of a proof that this happened through no fault of its administration.

We also suggest that something be said to remove the unfavorable impression made by the unfortunate experience of the institution with its instruments from the beginning of its history. How many costly instruments, supposed to be of the finest quality, have been procured, tested, reconstructed, found wanting and suffered to disappear from view, we cannot say without an examination of the records. But the recent easily accessible reports and documents throw some light on the later history of the subject.

The great 26-inch telescope, constructed about 1874, was found to be so defective that, on moving into the new Observatory, what was substantially a new instrument was constructed. We believe that nothing but the object-glass and, perhaps, some accessories of the old instrument were retained. Whose fault was this?

Perhaps the most necessary and important instrument the Observatory ever had was the 9-inch transit circle, constructed, we believe, some time in the sixties. It was found so defective in stability as to greatly impair the value of its results. Attempts to correct the defect proved unavailing, so radical changes were made in the instrument at a cost, if we mistake not, which could not have been greatly short of the original price. No sooner was it remounted at the new location than defects were found in its performance which, according to the annual reports, it took another year to remedy. In 1896 it is reported as again taken down for a period of five months in order that further extensive repairs might be made. The report of 1899 gives an elaborate account of renewed efforts during the first six months of the year to improve its performance, concluding with the statement: "In my opinion it should be restored as nearly as possible to its original construction." But this does not end the history. We learn from the present report that the instrument was again undergoing repairs and alterations for the first six months of the last fiscal year, and yet it winds up with the statement that "one of the defects still introduces liabilities to error which, though small, ought not to be tolerated in a modern instrument."

The defects in this instrument naturally led to the desire to have a better one. Accordingly, among the appropriations made for the new establishment was one of $10,000 for a meridian circle. This instrument was completed and mounted in 1897. We learn from the report before us that it exhibits a peculiarity of a kind so singular that it should interest physicists as well as astronomers. Its horizontal pointing changes so rapidly with the temperature that, by the aid of the delicate meridian mark, a variation produced by a change of a single degree in the temperature must be an easily measurable quantity. Consequently the instrument could be used as a fairly delicate thermometer. It is hardly necessary to add that observations with such an instrument cannot have much scientific value until the defect is corrected, and that the policy of the observers in not attempting serious work with it cannot be questioned.

The new 12-in. equatorial has proved unsatisfactory. There are also intimations that something is wrong with the prime vertical transit, and, altogether, the impression made on the reader is that, after seven years of effort to equip the Observatory with the best instruments, it is doubtful whether a single one of real importance, except the great telescope, is in order for first-class work. We hope something can be said to explain this history, which is without example. The Greenwich transit circle has been in continuous use for half a century except during a brief period of its early history, when some alteration was made in it. The small repairs which it has since required have caused no interruption in the continuity of its work. The instruments of the Pulkova Observatory have, for the most part, been in use since 1840, and it is believed that their results are to-day among the best attainable in astronomy.

Were only a single instrument involved in the case of our own Observatory, it might

well be set down to unavoidable misfortune. But so long-continued a history leads one to infer a cause, and we should be glad to see something said to efface the impression that the administration is at fault.

In the way of assistance we suggest a few other questions as worthy of careful consideration. It is understood that, when the Astrophysical Society of America chose its committee to confer with the Secretary of the Navy on the question of the Observatory, especial pains were taken to select men who had never been known to express any opinion on the subject. We are quite sure that the Society would like the Superintendent of the Observatory to state how he knows that in making the selection, it was the victim of misplaced confidence, and that the members were 'known to be inspired by a hostility to its organization.'

A cognate point is this: The membership of the Society includes a respectable and influential number of members who have been connected with the Observatory at one time or another in various capacities and who would be its natural defenders. Would not some of them have objected to the appointment of a hostile committee?

The greater number of our astronomers are the mildest of men, and glad to see their science promoted in every way. How does it happen that they, as a class, are moved by 'animosity' toward a national institution for promoting their science?

We wish also to discover every possible justification for the claim that "no person, no matter how eminent he may be in science, can pretend to be a friend of the Observatory or of science while attacking its organization." This is preceded by the statement that "the number of observations made at the old and new Observatories kept pace with those made at Greenwich." If the report had said that the Observatory during the past ten years, with less than half the personnel of Greenwich, had, on the average, done nearly one-half as much work, the critics might have inquired in reply whether this was not a slight exaggeration. They might also have inquired whether it was not desirable to take account of the quality as well as the quantity of the work, and whether in that respect the observations described in the annual reports of the last ten years could compare even with one-third of the work done at Greenwich. But when we find the head of the Observatory seriously believing that some comparison can be instituted between the output of the two observatories we see that he has, from his own point of view, just cause of resentment against the critics of the institution, and feel encouraged to believe that, when he has ascertained the facts, he will, as an act of justice, fair play and public policy, admit that the 'prejudices and animosities' of the astronomers have better grounds than he had supposed.

REPORT OF THE SUPERINTENDENT OF THE NAVAL OBSERVATORY.

[WE regret that we have room only for such portions of this interesting report as relate to astronomical work and the report of the board of visitors.]

DEPARTMENT OF ASTRONOMICAL OBSERVATIONS.

The work of the year in this department may be summarized as follows:

Professor William Harkness, who retired from active service on December 15, 1899, was succeeded in the astronomical directorship by Professor Stimson J. Brown, the senior professor of mathematics on duty at the Observatory. Professor Brown's first duty was as member of a board of examiners, to fill the vacancy caused by the retirement of Professor Harkness, by the selection of a suitable candidate for appointment as professor of mathematics in the navy. The labors of this board, of which Professor William Hendrickson, U. S. N., was senior member, resulted in the selection and appointment of Professor W. S. Eichelberger. In this connection it is pertinent to observe that the present condition of the astronomical staff of the Observatory is highly satisfactory, and gives promise for the future. The vacancies, caused by the rapid successive retirement of the older professors, have all been filled by young men of marked ability, and the Observatory has followed its traditional policy in this respect, and has every reason to anticipate a renewed activity and a period of harmony, industry and usefulness.

All the astronomical instruments of the Observatory have been steadily and continuously in use during the year on every clear night and day.

The XXVI.-inch equatorial telescope has been employed on the observation of difficult double stars, the satellites of the planets and the measurement of their disks, and on other objects suitable to an instrument of its power. This instrument was in charge of Professor Brown, assisted by Professor T. J. J. See, until December 15th, and has since been in charge of Professor See.

In the month of October, during the hazy weather common at that season, the images of celestial bodies were marked by great steadiness in the field of view, unusual at other times. Owing to this favorable condition, Professor See noticed on several occasions faint markings on the disk of Neptune, similar to the equatorial belts of the planets Jupiter and Saturn. The fine definition at this time was ascribed to the selective absorption of the haze caused by the smoke of forest fires, and an attempt has been made by Professor See and Mr. George H. Peters, the photographer, to reproduce artificially the same conditions by the use of a color screen. The idea of this application to the telescope was not wholly new, although it was believed to be so at the time. It is too early to speak definitely on the result of these experiments, except to say that the general effect of the use of a screen composed of two thin sheets of plate-glass, the space between them being filled with a solution of chloride of copper and picric acid, or a solution of bichromate or chromate of potash, seems to have the effect of absorbing the blue rays and removing the halo which surrounds bright objects in the field of a large achromatic telescope, and the image appears somewhat steadied. The color screen is now in use in observations of the diameters of the planets and measurable satellites.

During the year the double floor, which was appropriated for last year, designed to obviate the difficulty experienced from currents of warm air rising from the basement, has been finished, and answers every expectation, giving highly satisfactory results.

The IX.-inch transit circle was undergoing its periodical repairs and general overhauling from the beginning of the fiscal year until January 20, 1900, during which time the routine work of the sun, moon and planets was carried on with the new VI.-inch steel transit circle. Since the resumption of the regular work on the IX.-inch circle, Professor Skinner has had charge of the zone observations and Professor Eichelberger of the routine sun, moon and planet work, while the VI.-inch circle, in charge of

Professor Updegraff, has been under strict investigation, with a view to determining the causes of several faults made apparent by the routine work and probably unavoidable in a new instrument.

In the meridian work a total of 1,114 observations of zone stars and a total of 3,105 observations in the sun, moon and planet work have been made during the year.

The XII.-inch equatorial has been used for observations of comets, asteroids and other miscellaneous objects, and will soon undergo some extensive repairs and alterations.

Assistant astronomer George A. Hill has devoted the prime vertical transit to observations of α Lyræ and a small list of suitable stars in the investigation of the variation of latitude and the constants of nutation and aberration, and the same observer has used the new V.-inch steel altazimuth instrument principally as a zenith telescope for observations for latitude by Talcott's method, and for the declinations of stars of the American Ephemeris.

The 40-foot photoheliograph has been used in making daily photographs of the sun whenever the weather permitted, except after April 2d, during preparations for the observations of the total eclipse of the sun on May 28th.

By an appropriation of $5,000 the Observatory was able to undertake observations of the total eclipse of the sun on the date above mentioned. Two parties were sent into the field, and attention is respectfully invited to the detailed report of the astronomical director on this subject, and also to the recommendation for an appropriation to cover the expenses of a similar expedition this year, in the eclipse of May 17, 1901, which is approved and indorsed.

Preparations are now in progress for installing at the Observatory a new standard clock which shall be entirely freed from the influences of changes of temperature, and the recommendations of the astronomical director on this subject are approved.

The work of bringing up the publications of observations to date, which has been in arrears for several years, is being vigorously pushed, and the issue of the first volume of the new series of Washington observations, commencing with the first year of the Observatory's work on the present site, will soon occur, to be followed by the succeeding volumes in rapid succession. The delay in the publication of its work has been made a reproach to the Observatory, although the causes of this delay have been reasonable and unavoidable, but the most earnest and determined effort is being made to relieve the Observatory of a condition which has been used to its disadvantage in outside criticism.

The report of the astronomical director is herewith transmitted in full.

The department of magnetism has been discontinued, as noted in the last report of the superintendent. The buildings and instruments are, however, maintained in perfect order under the charge of assistant astronomer Theo. I. King. The Georgetown and Tennallytown Electric Railway has already installed a return wire which, it is reasonable to suppose, it intends sooner or later to use. When this road ceases to ground its powerful working currents, an attempt will be made to resume magnetic observations at the Observatory. The result is dubious. Moreover, the Observatory is to a lesser extent within the influence of the Chevy Chase road, which would continue to affect observations.

BOARD OF VISITORS.

As noted in my last report, and for the first time in its history, a board of visitors was appointed which visited the Observatory in June and again in September, remaining a few days at each visit. As the report of the board, which was not made

available to the Observatory until long after its substance had appeared in the public prints, was in the nature of an attack on the Observatory, I trust that it will not be out of place, in the report of the Superintendent, to touch upon its salient features.

The board was unfortunate in having the support of several zealous newspaper writers, by whom it has been made to appear, and I think that it is generally believed in the scientific world and by that part of the public which takes an interest in scientific affairs, that the presence of the board was in the nature of a visitation distasteful to the Observatory and inflicted against its will. As the Observatory has thus been made to appear in an odious light, I take the liberty of reminding the Bureau that not only the original conception of the board of visitors was a suggestion of the Superintendent, but the selection of the three astronomical members was concurred in by him because they were already the members of a self-constituted committee to conduct a gratuitous investigation of the Observatory, and known to be inspired by a hostility to its organization. It was hoped that by placing them in a position of official responsibility an impartial judgment could be obtained.

A criticism of the report may be very briefly summarized. The board made no examination or inspection of the Observatory except in the most casual way. To quote its own language, "Owing to the lack of printed material representing the recent work of the Naval Observatory, the board of visitors finds it practically impossible to form a satisfactory opinion of that work without devoting to the task an inadmissible amount of time and labor." Nevertheless, and without such an opinion, the board did not hesitate to recommend the most sweeping changes in the present organization, and it is noticeable that the report of the board deals exclusively with the question of reorganization, while that question had not been officially presented to it at all. As a guide to the board the following letter of instructions was addressed to it by the Department:

NAVY DEPARTMENT,
WASHINGTON, JUNE 28, 1899.

SIR: I have the honor to enclose you herewith a memorandum making certain suggestions which the Department wishes the board, of which you are the chairman, to have in mind in making an examination of the Naval Observatory. This memorandum is not intended to finally limit the investigations of the board, but to convey certain suggestions in regard to which the Department desires to be informed, and which, it is believed, may assist the board in its work.

JOHN D. LONG, *Secretary.*

Hon. WM. E. CHANDLER,
Chairman Board of Visitors, Naval Observatory, Washington, D. C.

[The points covered by the enclosure, which is too long for reproduction here, are meridian observations of the sun, moon and planets, spectroscopy and photography, chronometers, the Magnetic Observatory and the publications of the Observatory.]

Not one of the subjects proposed in the above memorandum received the attention of the board or was even mentioned by it. The whole report is taken up with the proposed reorganization, a subject which it had not been asked to consider at all, and for which it could only find a general authorization in the concluding paragraph of the Department's letter.

Notwithstanding that the board had no time to form an opinion as to the condition of work at the Observatory, the conclusion upon which it bases a recommendation for a revolutionary change of organization is found in the charge that the output, in published results, is not commensurate with an extravagant annual outlay. In other words, the board lays particular stress upon the delay in the publication of the annual volume, and bases its whole finding upon that fact.

The board makes a comparison between the Naval Observatory and the observatories at Greenwich and Harvard, selecting the former because it is supposed to cover nearly the same field, and the latter because it also undertakes large pieces of routine work which are beyond the reach of smaller observatories, because the resources of Harvard approach more nearly than do any other those of the Naval Observatory, and because all the details of the Harvard Observatory were readily available, its director being a member of the board.

I ask the attention of the Bureau to the following table, which gives an exact comparison of the three observatories chosen by the board, and which, almost without elucidation, confutes the sole and only charge made by the board against the efficiency of the Observatory upon which charge the only recommendation of the board rests.

Comparison of number and cost of scientific personnel of Greenwich, Harvard, and Naval observatories, previous to July 1, 1900:

GREENWICH OBSERVATORY.

Scientific personnel.	No.	Average.	Total.
Director	1	$5,000	$5,000
Chief assistants	2	2,550	5,100
First-class assistants	4	2,000	8,000
Second-class assistants	4	1,200	4,800
Magnetic superintendent	1	1,700	1,700
Assistant magnetic superintendent	1	1,000	1,000
Computers	23	325	7,475
Total	36	....	$33,075

HARVARD COLLEGE OBSERVATORY.

Scientific personnel.	No.	Average.	Total.
Director	1	$5,000	$5,000
Astronomers	6	2,000	12,000
Assistant astronomers	13	900	11,700
Computers	18	600	10,800
Total	38	....	$39,500

UNITED STATES NAVAL ACADEMY.

Scientific personnel.	No.	Average.	Total.
Astronomical director	1	$3,500	$3,500
Other professors of mathematics	4	2,700	10,800
Assistant astronomers	3	1,900	5,600
Computers	6	1,200	7,200
Photographer	1	1,200	1,200
Total	15	....	$28,300

A comparison of the figures in this table shows that the number of astronomers employed at the Naval Observatory is 5, at Greenwich 3, at Harvard 7. The Naval Observatory has the advantage of Greenwich and decidedly the disadvantage of Harvard. In the matter of assistants, however, the case is different. The total of assistants at Greenwich is 8, at Harvard 13, and at the Observatory 3; while the computers stand, Greenwich 23, Harvard 18, Naval Observatory 6.

In the years 1891 to 1893 the Observatory was removed from the site which it had occupied for nearly fifty years, to its present situation. The delays in building, the labor of dismounting and remounting the instruments, the repairs and alterations of the same and their subsequent installation, the removal of the records and Observatory property, and generally the labor involved in settling in the new place, absorbed the entire time of the whole very limited working force of the Observatory for several years. The publication of results, from this cause and from this cause alone, fell into arrears. The force of the astronomical staff, sufficient for current work in settled times, was totally inadequate to bring up back work when the work had fallen behind. It was simply a physical impossibility to keep up the publications, and to make the current observations and do the necessary work of removal at the same time. This and this alone is the cause of the delay in printing, and when the number of assistants and computers at the Observatory is contrasted with the numbers at Greenwich, and especially at Harvard, the delay is reasonable on its face. These facts were represented to the board, but are nowhere given in its report. The board, on the contrary, evaded and concealed them. It might have reasonably been shown that during the whole of this transition period current work was practically uninterrupted, and that the number of observations made at the old and new Observatories kept pace

with those made at Greenwich. But "owing to the lack of printed material the board found it impossible to form a satisfactory opinion upon that work, without devoting to the task an inadmissible amount of time and labor." The facts were laid before the board and ignored by it. They would have shown to the credit of the Observatory.

It is needless to say that the figures in the above table are not given by the board in its comparison of the three observatories named as they are given here. The board had to make a case against the Observatory, and the charge of extravagance of outlay in proportion to the output of results had to be substantiated. Accordingly, the whole staff of the Observatory, scientific and lay, is contrasted with that at Harvard, and the numbers are brought to an equality by adding in the artisans and laborers employed about the buildings and grounds, Harvard having practically none. By this process the astronomical personnel of the Observatory is shown to be one in excess of that at Harvard, and the salaries are compared on this basis, greatly to the disadvantage of the Observatory. This enumeration also charges the Observatory with two 'directors' for the same obvious reason. Although the board had no time to form an opinion, it should have learned, if it could have assimilated the information which it received, that the Observatory, like other naval establishments, has but one 'head,' and that the astronomical director of the Observatory is the head of the astronomical department, just as a naval officer is the head of the department of nautical instruments. To charge two 'heads' to the Observatory in order to increase the apparent extravagance of maintenance is clearly a perversion of fact. If the Observatory has two heads, then it has eight heads, one for each department, and including the superintendent.

The attention of the Bureau is asked to a comparison of salaries, shown in the above table, which forms the basis of the board's charge of extravagance. At both Greenwich and Harvard the salary of the director is $5,000. At the Observatory, using the board's own method of comparison, the corresponding salary is $3,500. But, by the ingenious device of a 'dual head,' the board increases it to $4,000 and then doubles it. Naval officers receive their pay, whether they happen to be on duty at the Observatory or elsewhere; but the board chooses to assume that the salary of every professor of mathematics in the navy, active or retired, except two at the Naval Academy, is chargeable to the expenses of the Observatory. It therefore charges in its exhibit the salaries of officers on the retired list, and the salary of one officer, still on the active list, whose connection with the Observatory has long since definitely ceased for cause. By such flimsy expedients as these the expense column is easily swelled. It might be swelled to any amount desired by simply charging against it the salary of any or every living officer of the navy, active or retired, who had ever been on duty at the Observatory. It is in the lower grades particularly, however, that I ask a fair comparison of salaries at the three institutions selected by the board. At Greenwich, for example, computers receive an average of $325 per year, less than one-half the pay of our laborers, and less than the remuneration of any human being doing skilled work in the United States. At Harvard computers receive an average of $600, less than the pay of any person in the United States service. These computers are largely women, who can be got to work for next to nothing. Now the Observatory pays its employees at exactly the same (or in some cases less) rate as in other branches of the government service in corresponding grades. To charge extravagance against

the Observatory because its employees are paid according to a rate fixed by law for the public service at large is clearly disingenuous and tending to mislead.

The whole report of the board is colored by the evident intention of making as strong a case against the Observatory, and in favor of its own plan of reorganization, as possible.

On page 6 the board objects to transferring responsibility of direction from the astronomical director to a committee, and then, on pages 7 and 8, recommends that the board of visitors 'shall prepare and submit to the Secretary of the Navy regulations prescribing the scope of the astronomical and other researches of the Naval Observatory and the duties of its staff with reference thereto.' In other words, the duties which should belong to the astronomical director, if he is to be held responsible for the astronomical work of the Observatory, are to be transferred to the board of visitors. Furthermore, on page 14, it is proposed that the board of visitors shall have power to make 'necessary changes,' apparently not only in the work, but also in the personnel.

On page 8 objection is made to retiring astronomers at 62 years of age, as is now done, and on page 6 it is specifically recommended that under the proposed new arrangement the astronomical staff of the Naval Observatory are to 'hold their offices until their successors are appointed,' or, in other words, they are to have no tenure of office at all, and to be liable to dismissal at any moment.

The pay table on page 9 proposes to give the astronomical director $6,000 a year, and the director of the Nautical Almanac, $5,000, making a total of $11,000 a year, for the same duties which were then performed by Professor Harkness for $3,500 a year. In view of the distinct charge of extravagance against the present administration, this proposal is only ludicrous. It is difficult to believe that it was intended to be taken seriously.

On page 12 it is asserted that the 9-inch transit circle was not then in use, although the board knew that it was simply undergoing periodical temporary repairs, and would be brought into use again as soon as they were completed.

On page 13 it is asserted that none of the directors of the Greenwich or Harvard College observatories 'have ever resigned to accept positions elsewhere,' but the author of the report forgets to mention that one of the Greenwich astronomers royal did resign.

On page 15 it is indirectly stated that when an observer is not actually observing he is only doing clerical work, which is untrue. The reduction of astronomical observations is not clerical work within the ordinary meaning of that phrase.

The statement on page 30 respecting the personnel of the Observatory board established by Rear-Admiral John Rogers is wholly erroneous. That board comprehended the entire astronomical staff of the Observatory.

In the list of professors of mathematics, given on page 41, Professor H. M. Paul is stated to be attached to the Naval Observatory, when in fact he is attached to the Bureau of Yards and Docks.

An historical sketch of the Naval Observatory, written by an individual member of the board, with the avowed purpose of showing that the system under which the Observatory has been administered since its foundation is entirely defective, is appended to the report. It is a sufficient criticism of this sketch to say that a system which, from a most modest beginning, has built up one of the few great astronomical institutions of the world, and which has produced the two most eminent living astronomers in America, can not be wholly bad.

It is particularly worthy of note that the board actually proposes to remove the affairs of the Observatory from Government control. The irresponsible governing authority of a public institution is to be 'a board of visitors independent of Government control, but having power to make necessary changes.' With the exception of this preposterous proposal, I will dismiss the plan of reorganization proposed by the board with the simple statement that subsequent events have made it impracticable, or at least highly unlikely, to be seriously considered now. To apply it at the present time would be, not to build up, but to tear down.

A determined effort was made by the board to prevent, if possible, the appointment of new men to fill the vacancies created by the retirement of the older professors of mathematics at the Observatory. New offices were created in the board's plan of reorganization, at enormous salaries. Notwithstanding the efforts of the board to prevent it, these vacancies have all been filled in line with the traditional policy of the Observatory, which has always been to take for its staff young men of promise whose career was before them, in contrast with the plan, recommended by the board, of appointing at once to high office men whose scientific reputation was already established, and whose prejudices and animosities were mature and confirmed.

I have ventured to touch in brief upon the report of the board of visitors in a manner which I trust does not transcend the legal limitations of this report, because, while the Observatory has been made the object of adverse criticism in the report, the friends and supporters of the board have not hesitated to assail it in attacks in the public prints, some of which have been extremely abusive and obviously dictated by pure malice, and with the knowledge that a reply in kind was impossible. This report furnishes the only means of replying to these attacks, which are and have been perennial, culminating in force whenever, as in the present instance, circumstances seemed to justify a reasonable anticipation of success.

The Observatory staff is now complete. The excuse afforded by the retirement of the older professors of mathematics no longer exists. For the present, at least, no person, no matter how eminent he may be in science, can pretend to be a friend of the Observatory or of science while attacking its organization. I do not mean to say that the Observatory should be exempt from criticism; but such criticism, in order to be of any benefit, must be made in a spirit of fairness, and not in a spirit of animosity. The Observatory invited such criticism from the recent board of visitors, and its invitation was slighted.

The Observatory is making an earnest and honest effort to correct faults which have, in most cases, arisen from circumstances not wholly within its own control, as the board very well knew, but omitted to point out. It is only reasonable to ask that it be allowed a fair field for its efforts.

The experience with the recent board of visitors was not such as to encourage the hope that much good can be gained by a repetition of the experiment. Nevertheless, I recommend that a board of visitors be appointed from time to time, as may be convenient to the Department, not to act in an arbitrary and irresponsible capacity of authority, 'free of government control,' as recommended by the late board of visitors, but to give the Observatory the benefit of its counsel and to give the scientific world an insight into the actual workings of the institution.

[The following extracts from the report of the Astronomical Director refer to the instruments whose work is not summed up in the preceding report of the Superintendent.]

THE 6-INCH STEEL TRANSIT CIRCLE.

[Professor Milton Updegraff, U. S. N., in charge.]

* * * * * *

This instrument is made entirely of steel and mounted very solidly, so that the constants might reasonably be expected to be unusually steady. In the case of the level and collimation this expectation has been realized, but not in the case of the azimuth. Both the collimation and the level are remarkably uniform, excepting that on one or two occasions the latter has shown slight though anomalous changes. A series of experiments made in November, 1899, showed that the variation of the azimuth keeps pace regularly with the variation of the temperature of the steel in the microscope bearers on which the pivots rest. This variation is not, however, a linear function of the temperature, but is less per degree at low than at high temperatures. The change of azimuth per degree of temperature (Fahrenheit) during the earlier part of its use seems to have been $0^s.032$. Since the instrument is provided with a meridian mark to the north, this variation of the azimuth has been productive principally of inconvenience rather than inaccurate work; but the change is too great to make the instrument a suitable one for fundamental work. The instrument will in the near future be entirely dismounted and a careful investigation made in the hope of finding the source of this variation.

THE PRIME VERTICAL TRANSIT INSTRUMENT.

[Assistant Astronomer George A. Hill, in charge.]

The work on this instrument has been devoted to observations of α Lyræ and a small list of suitable stars for the purpose of investigating the variation of latitude and the constants of nutation and aberration. The number of observations is as follows:

α Lyræ	89
Other stars	75

A careful investigation of the level-constant, with a special reference to the coincidence and parallelism of the axis of the pivots, is in progress, but the material is not yet sufficient to determine whether any defect exists in regard to this which is of sufficient magnitude to affect the observations.

THE 5-INCH STEEL ALT-AZIMUTH INSTRUMENT.

[Assistant Astronomer George A. Hill, in charge.]

This instrument is used principally as a zenith telescope for observations of latitude by Talcott's method and the declinations of the stars of the American Ephemeris. Of the former there have been made 86 observations of α Lyræ and three of miscellaneous stars, which are reduced up to date, and the results in January, 1900, together with the material from the prime vertical instrument, sent to Professor Albrecht. Of the declinations of Ephemeris stars 330 observations have been made, and the reductions are completed up to the end of the calendar year.

The results have not yet been subjected to sufficient study to determine the quality of the instrument for obtaining absolute declinations, for which purpose the general form of the mounting is admirably adapted. When its usefulness in this field is established I propose to separate the work of the two instruments and employ more observers in this important line of observation. I have not thought it expedient to attempt this until the arrears of publication are brought up—a task on which all the available force of the Observatory is now concentrated.

THE 40-FOOT PHOTOHELIOGRAPH.

[Photographer George H. Peters, in charge.]

The series of daily photographs of the sun has been continued, weather permitting, except after April 2d, when they were interrupted by the preparations for the observations of the total eclipse in May. Nega-

tives were obtained on 81 days, showing sun spots on 18, distributed as follows: Two in September, two in December, five in January, five in February, three in March and one in April. Visual observations of the sun in May indicate the same low state of solar activity.

STANDARD CLOCK.

Preparations are now in progress for installing a standard clock in a hermetically sealed case to be kept in a double-wall chamber at a constant temperature. The device for keeping the temperature constant is entirely similar to that now employed so successfully in the temperature room for testing chronometers. I consider this subject as one of the most important for the future of the fundamental work of the Observatory, and no pains or expense ought to be spared in securing the best possible performance of a standard clock under the conditions above described. I regret that the preparations for the eclipse so completely occupied the resources of the Observatory that this important matter has had to be laid aside until the present time.

---

*AIMS AND METHODS OF STUDY IN NATURAL HISTORY.**

I invite your attention to an old but still fruitful topic, namely, the aims and methods of study in natural history. It is a well-worn theme, but one that will retain its interest to the naturalist so long as natural history remains a progressive subject; and I venture to think that it was never more timely than at the present period of intense activity in natural science, of rapid development of new aims and methods, and of continually shifting point of view. How great the changes have been in the last twenty or even ten years is, I dare say, hardly realized by many of the younger generation of naturalists to-day. To appreciate their full extent one must be old enough to have passed his student days in the sixties and seventies, at a time when it was still possible to discuss the truth or error of the evolution theory; when the germ theory of disease was itself no more than a germ; when a gastrula or a karyokinetic figure was a thing to be spoken of with bated breath, but not to be looked upon when there were no oil-immersion-lenses or Abbe illuminators, no automatic microtomes, no ribbon-sections, no chromosomes or centrosomes, no shaking of eggs, no 'taxes' or 'tropisms'; when to adopt the career of a naturalist was to face the imminent prospect of extinction in the struggle with the environment, and to incur the half-admiring, half-contemptuous compassion of one's relatives and friends.

Speaking as I am in the presence of some of those who guided my own first tottering footsteps along the pathway of science, I feel some hesitancy in claiming a place among those veterans of the old guard; but I am nevertheless able to recall days when we had to do without all the things I have mentioned, as well as a good many others, both material and spiritual, that are now considered the very bread of life in the day's work. I will confess, too, that I am old enough to be at times lost in wonder at the child-like serenity with which the modern student will accept many of these matters, which cost such travail of the spirit, and at the distant epoch to which I have referred would have produced a sensation throughout the scientific world. When, for instance, Kleinenberg made the famous declaration 'Es gibt gar kein mittleres Keimblatt' it seemed to us that the sky must fall on such a blasphemy. We have changed all that. Cite those memorable words to-day, at the climax of your cautious discussion of the

* Presidential Address delivered at the annual dinner of the American Society of Naturalists, Baltimore, December 28, 1900.

germ-layer theory, and your *fin de siècle* student merely remarks stolidly, as he reels off a yard or two of ribbon-sections from his Minot microtome, "Of course not; but what is the use of talking about such an antediluvian myth?" It is enough to make Balfour turn in his grave!

I do not propose to review the advance of discovery in recent years, but only to offer a few reflections on the progress of our aims, methods and standpoints, taking as my point of departure Louis Agassiz's delightful little book, entitled 'Methods of Study in Natural History,' published in 1863. In this work we find a clear and simple exposition of the aims and methods of natural history as they appeared to a great naturalist and teacher before the theory of evolution had wrought its wonderful transformation in natural science. We all know that, as far as that theory was concerned, Agassiz ranged himself on the side of a losing cause, believing, to quote his own words, that naturalists were chasing a phantom in their search after some material gradation among created beings such as that theory demanded, though he was constrained to the admission that 'this notion' had a certain fascination for the human mind. I am here concerned with Agassiz's position on this question only in its bearing on his aim and method. It was Agassiz's aim, first, to observe phenomena with all possible accuracy; and, second, to arrange and classify them in order to discover the 'natural affinities' of living things. His method, on the all-importance of which he was never weary of dwelling, was that of his master, Cuvier, *comparison*. "The true method of obtaining independent knowledge" he says "is this very method of Cuvier's—comparison." "The education of a naturalist now consists chiefly in learning how to compare." It was not Agassiz's aim to analyze and explain phenomena, as Darwin was attempting to do. His whole theory of organic creation precluded such an aim; for existing phenomena of life were viewed as the result, not of progressively operating causes, but of special creation, and 'natural affinities' among living things were but the expression of creative thought. It was enough for him to observe, compare and classify. In his work one is everywhere struck with the eager and enthusiastic delight that he took in the facts of natural history for their own sake. The key note of Agassiz's work was, in short, *the love of nature*, and his remarkable success as a teacher was mainly due to his power of inspiring a like enthusiasm in others. Such, in few words, were what seem to me the characteristic features in Agassiz's aim and methods. They may have for us later naturalists a useful lesson, both in their agreement with, and their contrast to, some of the latest *dicta* of modern writers on scientific method.

Leaving aside for the moment the subject of experimental physiology, we may say broadly that the progress of natural history since Agassiz's time has been along three general lines of study, though no very definite line of demarkation between them can be drawn. First came the development of comparative morphology, dominated by Agassiz's method of observation and comparison, but largely inspired by a theory of organic forms that was the very antipode of his own. Here belong the elaborate and exact modern investigations on general and systematic zoology and botany, on geographical and geological distribution and on comparative anatomy and embryology. In all these, a leading motive was to search for natural affinities and to interpret them in accordance with the theory of evolution. It has been a laborious and persistent quest, carried forward on a vast scale; and there is now hardly a corner of the plant or animal kingdom into which it has not been pressed. Its point of departure was primarily given by the comparative anatomy

of existing forms of life, supplemented by that of extinct forms. Almost from the start, however, it was evident that the data derived from those sources were sufficient without the additional evidence afforded by the facts of embryological development. Despite the high degree of validity possessed by the paleontological evidence, the record is, and is likely always to remain, too meager to guide us to the broader results we seek. Without the aid of embryology, comparative anatomy, with all its wealth of data, gives us hardly a hint of some of the most fundamental relations of living things. The high value of the embryological evidence was therefore early recognized; and with the progress of research it played a more and more important rôle in the examination of genealogical problems.

It seems a singular irony of fate that Agassiz, an anti-evolutionist, should have singled out as the most important result of his life-work a discovery in embryology, which, in connection with the generalizations of von Baer and Darwin, was destined to form one of the watchwords of a coming generation of evolutionists. "I have devoted my life to the study of Nature, and yet a single sentence may express all that I have done. I have shown that there is a correspondence between the succession of forms in geological times and the different stages of their growth in the egg—this is all." In another place he urges young students to turn to the study of embryology; for here, he says, lies 'an inexhaustible mine of valuable information—where we shall find the true facts by which to determine the various kinds and different degrees of affinity which animals bear not only to one another, but also to those that have preceded them in past geological times.' How little he foresaw the use which embryologists were soon to make of this principle or the lengths to which they would go in its application. It was in that very year that Fritz Müller published the famous little book entitled 'Facts for Darwin,' which contained the first clear outline of the recapitulation theory and marked the beginning of the embryological search for genealogies, continued with so much ardor by Haeckel, Semper, Claus, Dohrn, Balfour and a hundred others. Many of us have eagerly followed the phases of that long quest or have sought to make our own modest contributions to it. We know how many puzzling problems of comparative morphology it has brought to a solution, how great an impulse was given to the investigation of natural affinities by the formulation of the recapitulation theory by Müller, Haeckel and their followers. I would be the last to question the immense interest and value of the results that have thus been achieved in the field of genealogical inquiry. And yet I believe that when these results, together with those derived from all other sources, are broadly viewed, we are constrained to the admission that comparative morphology as a whole has thus far solved only minor problems of descent, and that naturalists as a body are beginning to turn their attention in other directions. Let any one who doubts this compare the present attitude of naturalists towards some of the more general problems of descent with that of fifteen or twenty years ago. At that time the burning questions of zoological morphology centered in far-reaching genealogical hypotheses such as the *Gastræa* theory, the *Trochophore* theory, the *Nauplius* theory, the origin of vertebrates, the origin of metamerism, or the derivation of bilateral animals from medusoid or polypoid forms. They still remain questions of very high interest, but they are no longer the leading questions of the day; and we may as well admit the truth that interest in them is beginning to wane, temporarily perhaps, but unmistakably.

It will be worth our while to inquire into the reasons for this.

First, we cannot repress a certain feeling of dissatisfaction at the vagueness of our conclusions regarding many of these major problems. Our knowledge of the anatomy and development of the leading types of life is still very far from complete—indeed, the field before us remains so vast that we may never hope to exhaust its possibilities of research. We have, nevertheless, gained a fairly clear view of the general outlines of the system. But have we reached substantial agreement regarding the natural affinities of the great types? In a few cases, yes; but I think the candid naturalist must also reply, in most cases, no. How is it with that time-honored problem, the origin of vertebrates, in one way the most interesting of all, involving as it does our own remote ancestry? How is it with the origin of annelids or mollusks, of echinoderms, of platodes, of round worms or molluscoids? What are the historical relationships of the higher types to the Cœlenterata, of bilateral to radial forms, or of Metazoa to Protozoa? I dare say most of the morphologists present hold more or less definite views on these questions—if I, for one, am charged with holding such views on the zoological side I shall not defend myself or deny that all these are questions of high interest to me. But have we reached definite conclusions on which we are substantially agreed? I fear that a general discussion of the zoological members of this society would elicit but too emphatic a negative reply, and that a similar symposium of our botanical brethren would not set us a better example of unanimity. I do not doubt that the progress of research will in time bring us much nearer to a definite solution of these great problems; though it lies in the nature of the case, that we can never attain complete certainty. In the mean time, we may as well admit that in the application of the embryological evidence to the broader problems of descent the recapitulation theory has encountered so many difficulties, undergone so many modifications and limitations, that investigators have in a measure wearied of their wanderings through the scholastic mazes of ancestral and secondary characters, of palingenesis and cenogenesis, of primary and adaptive forms and the like, and have sought for new interests and fresh motives of study. This is clearly apparent in the changed character of the more recent papers in embryology, which devote far less attention than those of ten or fifteen years ago to 'genealogische Betrachtungen' that once formed their inevitable climax. The relative decline of interest in genealogical questions is partly due, I think, to a healthy reaction against the inflated speculation into which morphologists have too often allowed themselves to fall; but it is also in large measure a result of the growing feeling that the solution of the broader problems of genealogy still lies so far beyond our reach that we would better turn for a time to the study of questions that lie nearer at hand and are, to say the least, of equal interest and importance.

We here arrive at a consideration of the two other great lines of progress to which I have referred. The first of these includes the modern developments of the cell theory, which have perhaps contributed equally with the evolution theory to the unification of biological knowledge. I need not dwell on the fundamental importance or the fascinating interest of the general results that have been attained in this field. The point on which I would lay emphasis is that investigation in this direction has only in very minor degree been inspired by the evolution theory or influenced by the historical point of view. The study of the cell, whether morphological or physiological, has been inspired by the desire to penetrate more deeply into the mechanism of

the existing living body. It has established a fundamental unity in the organization and modes of activity of living things, but it has thus far taught us little or nothing regarding their origin and progressive transformations. The interest of the results of cell-research, therefore, is of a different kind from that attaching to the genealogical problems of comparative morphology, and the one has grown, in some measure, at the expense of the other.

A no less potent influence has been the rapid infusion of experimental methods into morphological research, which forms the third line of progress in question, and is fast becoming the characteristic feature of latter-day biology; and with this we may briefly regard the far older subject of experimental physiology. When we regard the novelty and importance of the results already attained through these methods, it seems strange that morphologists were so long content to leave them to the almost undisputed monopoly of the physiologists; and I think that zoologists must admit further that, until recently, they have lagged behind the botanists in this regard. It would, however, be wide of the mark to maintain that experimental methods in morphology are a new product of the day. Did not Bacon, in the 'Novum Organum,' urge that living things are especially adapted for experiment, and in the 'Nova Atlantis' even project a scientific institution for experimental researches with reference to the problem of variation?* More than a century before our time Trembley, Bonnet and Spallanzani showed how rich a field lay in the experimental study of regeneration; and Darwin later taught us what a wealth of suggestive results could be drawn from the long-continued experiments of breeders of domestic plants and animals. Nevertheless, it is only very recently that a definite program of experimental morphology has been laid out, and that naturalists have begun to address themselves seriously to the task.

The revival of experimental methods in morphology is only in part due to a reaction against genealogical speculation. It is in at least equal measure due—and here we touch on a point that is vital to my present purpose—to the closer relations that have sprung up between morphology and physiology, and to the *development of comparative methods on the part of physiologists.* Animal physiology, long confined almost exclusively to the study of vertebrates, at last broke away from its earlier traditions and entered upon a new career, in the course of which it amalgamated with morphology. The traditional line between morphology and physiology thus faded away in zoology, as it had earlier done in botany, as naturalists advanced from either side into a neutral zone of inquiry devoted to the physiology of the lower animals and of the cell, to the activities of one-celled organisms, and to experimental studies on regeneration and development, and on cell-morphology; while in the study of habit, instinct, variation and inheritance the psychologist and even the sociologist have made common cause with us. We may well congratulate ourselves on such a solidification of aim and on the accompanying increase in the exactness and order of our method, and this not merely because of the value of the results attained, but in no less degree through the revival of interest in natural history, in the older sense of the word, that has accompanied it. We see the signs of this revival in many directions—in precise and far-reaching inquiries into the habits and instincts of insects and birds, and the life of animal communities; in renewed and more accurate ecological studies on plants and animals of almost every group, in the increasing interest in systematic zoology and botany, in the extended examination of the plankton of inland waters and the sea, in the rapid

* Osborn, 'Greeks to Darwin,' pp, 92, 93.

development of exact statistical methods in the study of variation, and in many other ways, among which we should not forget the mention of the development of courses of instruction in the so-called 'Nature-study,' and the recent appearance of admirable text-books in which anatomical detail is largely—perhaps too largely—subordinated to the older natural history. I think, too, that we have a right in this connection to point to the influence that such associations as this Society have exerted in widening the range of common interests and fostering the spirit of scientific fellowship and cooperation.

With these changes has come a better understanding between the field naturalist and the laboratory morphologist and physiologist, who in earlier days did not always live on the best of terms. I shall never forget the impression made on me many years ago, shortly after returning from a year of study in European laboratories, by a remark made to me in the friendliest spirit by a much older naturalist, who was one of the foremost systematic and field naturalists of his day, and enjoyed a world-wide reputation. "I fear," he said, "that you have been spoiled as a naturalist by this biological craze that seems to be running riot among the younger men. I do not approve of it all." I was hardly in a position to deny the allegation; but candor compels me to own to having had a suspicion that while there may have been a mote in the biological eye, a microscope of sufficient power might possibly have revealed something very like a beam in that of the systematists of the time. However that may have been, it is undeniable that at that period, or a little later, a lack of mutual understanding existed between the field naturalist and the laboratory workers which found expression in a somewhat picturesque exchange of compliments, the former receiving the flattering appellation of the 'Bug-hunters' the latter the ignominious title of the 'Section-cutters,' which on some irreverent lips was even degraded to that of the 'Worm-slicers'! (For the sake of completeness it may be well to add that at a later period the experimental morphologists fared no better, being compelled to go through the world under the stigma of the epithet 'Egg-shakers.') I dare say there was on both sides some justification for these delicate innuendoes. Let us for the sake of argument admit that the section-cutter was not always sure whether he was cutting an *Ornithorhynchus* or a pearly *Nautilus*, and that at times perhaps he did lose sight of out-of-doors natural history and the living organism as he wandered among what Michael Foster called the 'pitfalls of carmine and Canada balsam'; but let us in justice mildly suggest that the bug-hunter, too, like Huxley's celebrated old lady, was sometimes a trifle hazy as to whether the cerebellum was inside or outside the skull, and did not sufficiently examine that hoary problem as to whether the hen came from the egg or the egg from the hen, and by what kind of process. The lapse of time has in truth shown that each had something to learn from the other. The field naturalist came to realize that he could not attain right conclusions in the investigation of the larger problems before him without more thorough studies in anatomy and development. The laboratory morphologist learned better to appreciate the fact that his refined methods of technique are after all but a means toward the better understanding of the living organism and its relation to its environment. On both sides, accordingly, the range of common interests and sympathies was extended; and some of the splendid monographs of recent years bear witness to the value of the results that have flowed from the combination of anatomical, embryological, systematic and ecological research.

But now, in the last place, we encounter in the recent writings of some of the experimental morphologists a singular attitude of mind toward other methods of study and, in particular, toward the comparative method and the historical point of view in biology generally, for it is seriously maintained that the scientific study of organic nature is possible through experiment and through *experiment alone.* That I am not overstating the case will be evident from the following citations from recent utterances by an eminent leader in this field. "The comparative method in morphology," he says, "is in itself not science, but only a preparation for scientific work." Speaking for the self-styled 'rational morphologists' he says, "We have not *a* method of scientific morphology, but *the scientific morphological method.* There is but one productive method, and that is our method." The historical point of view in comparative morphology is of wholly minor value. Even could we accurately determine the ancestral origin of plants and animals—which in point of fact we cannot do—we should still not have solved the real problem—namely, the laws in accordance with which evolution has taken place. The most complete acquaintance with phylogeny would give us only an ancestral portrait-gallery, nothing more than a 'photograph of the problem.' Only through systematic experiment can we unveil the nature and limits of the power of transformation that lies at the root of the evolutionary process.

We may as well admit forthwith that there is a large element of truth in this bold claim, and it is well to recall how prominent a place the experimental evidence of evolution held in Darwin's mind. The history of science shows incontestably that only through experiment, through deliberately calculated and precise alterations in the conditions under which phenomena occur, can we attain the limits of scientific analysis. So long, therefore, as the naturalist limits himself to the study of vital phenomena under natural conditions, he falls short of the highest ideal of scientific investigation. For my part, I am wholly ready to admit that the introduction of experimental methods into morphology is the most momentous step in biological method that has been taken since the introduction of such methods into physiology by Harvey and Haller. As regards the comparative method, I do not overlook the force of the argument that when comprehensive conclusions are attained by the mere elimination of facts that are not common to all the individual cases compared, those conclusions must have a more limited content than the collective data on which they are based, though I suspect that it would not require a very long search to discover a fallacy lurking here. But seriously to maintain that the non-experimental comparative study of nature is not science is an efflorescence of enthusiasm at which one could hardly repress a smile did it not involve so serious a blunder.

Now I certainly shall not undertake such a work of supererogation as a defense of the comparative method in natural history. Moreover, the statements cited were, I believe, intended mainly as a protest against too free genealogical speculation, and perhaps conveyed more than their author really intended. Yet the undoubted truth that they embody is masked by a form of expression so misleading, that even before this audience of naturalists I shall venture to place beside them the words of one or two of those best qualified to pass judgment on scientific method in the domain of physical science, which may rightly claim to be the experimental science *par excellence.* Helmholtz, in a discourse on the relation of natural science to general science, delivered at Heidelberg forty

years ago, said: "It is not enough to be acquainted with the facts; scientific knowledge begins only when their laws and causes are unveiled. Our materials must be worked up by a logical process; and the first step is to connect like with like and to elaborate a general conception embracing them all. Such a conception, as the name implies, takes a number of single facts together, and stands as their representative in our mind. We call it a general conception, or the conception of a genus, when it embraces a number of existing objects; we call it a law when it embraces a series of incidents or occurrences." What is the first example by which Helmholtz illustrated his meaning? It is one drawn not from experimental science, but from comparative anatomy, namely, the correlations of structure shown by the Mammalia. What was Helmholtz's estimate of the historical point of view in biology? Here are his own words, spoken ten years after the appearance of the 'Origin of Species': "The facts of paleontological and embryological evolution were enigmatical wonders as long as each species was regarded as the result of an independent act of creation, and cast a scarcely favorable light on the strange tentative method which was ascribed to the Creator. Darwin has raised all these isolated questions from the condition of a heap of enigmatical wonders to a great consistent system of development, and established definite ideas in the place of such a fanciful hypothesis as, among the first, had occurred to Goethe, respecting the facts of the comparative anatomy and the morphology of plants."

But, the 'rational morphologist' may reply, these words were spoken thirty years ago, and conditions have profoundly changed since Helmholtz passed this too favorable judgment. Let us see. In his address on the 'Principle of Comparison in Physics,' delivered before the German Association of Naturalists and Physicians at Vienna in 1894, that brilliant and versatile mathematical physicist, Ernst Mach, said: "Comparison, as the fundamental condition of communication, is the most powerful inner vital element of science." What is his first illustration of this truth? Again, as in the case of Helmholtz, it is drawn from non-experimental comparative morphology—from comparative anatomy and comparative embryology. "If it is not customary," he continues, "to speak of comparative physics in the same sense that we speak of comparative anatomy, the reason is that in a science of such great experimental activity the attention is turned away too much from *contemplative* element. But, like all other sciences, physics lives and grows by comparison."

It is needless to multiply such statements. Every really rational naturalist must admit that there is but one sane position to adopt, namely, to welcome any and every method by which our knowledge of organic nature may be advanced and unified. No one, I trust, will understand me to advocate the indiscriminate accumulation of facts—for this is not method, but the absence of method. The essence of science is not the accumulation of knowledge, but its organization. Observation and experiment give us our materials, but it is the comparison and correlation of those materials that first build them into the fabric of science. As I regard the matter, it is therefore a reversal of the true standpoint to regard biological classification, in the broadest sense of the term, as no more than a preparation for experiment. Let us, however, admit that our science is entering on a phase in which experimental methods seem destined, and rightly so, to take the leading rank, and that to them we may probably look for the greatest advances that are to be made in years to come. Let us, too, admit that our existing systems of classification, our views

of genealogical relationship, are incomplete, are in many respects still hypothetical and often misleading; that our methods of study have not been sufficiently exact; that a little judicious clipping of the wings of our scientific imagination will render its flight safer, even though it may not soar so high. But let us not depreciate the importance of the comparative study of normal phenomena to which biology already owes so many brilliant triumphs, and which, as we may confidently hope, has still so many future achievements in store. The true aim of the naturalist is to understand the conditions of living forms as they now exist and have existed in the past; but what are these conditions if not the result of an illimitable series of experiments, carried on by nature since life began? Under what other interpretation has the theory of natural selection any meaning? Comparative morphology and physiology but record and coordinate the results of these experiments. The experiments performed in our laboratories but supplement those that have taken place and are always taking place in nature, and their results must be wrought into the same fabric.

One final thought, and I have done. I have said that the key-note of Agassiz's life and work was his love of nature; and in this respect I believe he was typical of the great naturalists of every age. It has of late become the fashion in some quarters to look with a certain condescension on what is styled the 'sentimental side' of natural history, on that keen primary interest in biological phenomena for their own sake, apart from their scientific analysis, that was characteristic of so many of the earlier naturalists. I can but believe that such an attitude shows a lack of insight into the real motives and sources of inspiration of all great observers and discoverers. Every critical analysis of the progress of science leads to a recognition of the vital importance of the imaginative faculty in all research of a high order; and in this regard great masters of creative science, such as Faraday or Darwin, have rightly been placed beside the great masters of creative art. But this faculty is nearly akin to the esthetic sense. Karl Pearson, in his admirable 'Grammar of Science' remarks, "Both works of art and laws of science are the product of the creative imagination, both afford material for the esthetic judgment." Pearson is here referring, it is true, to the sense of beauty and harmony aroused by the discovery and contemplation of natural law. Beyond this, however, we must recognize that there is no more potent spring of scientific research than a lively interest in the facts—in other words, the esthetic satisfaction that lies in the mere observation of natural phenomena. Read the intimate records of the lives of great discoverers in every field of science, and you cannot fail to be struck with this. From this source flows the impulse to analyze by experiment, to correlate by comparison and thus to discover law. The primary impulse of the naturalist is thus given by the love of nature; and I believe that the scientific naturalist should welcome every movement toward the cultivation of general interest in natural history. We may therefore regard it as a happy omen for the future of our science that in every direction we see the signs of increasing interest in field work, in nature-study and in the teaching of natural history in our schools. It would be an evil day for the more advanced and precise study of biology when it came to be regarded as actuated by motives having nothing in common with the love of nature that inspired such men as Darwin, Agassiz, Audubon and Gray; but we need not fear that such a day will come. For my part, I believe that the newer experimental study is better calculated to foster an interest in nature than much of the

minute anatomical and embryological work that has played so great a rôle in the laboratory methods of comparative morphology. These methods were a healthy reaction against the superficial character of much of the earlier work; they form the indispensable basis of all exact and thorough training in biology; but too often in our courses of instruction they have been carried to such a point that the student has lost himself amid anatomical detail of a kind as dry and formal as that of the old-fashioned systematic museum-study. Experimental research is already, I believe, exerting the happiest influence on our methods of teaching by showing how indispensable to a course in comparative morphology is the consideration of physiological phenomena and a study of the living organism.

I cannot better close than with the words that an eminent zoologist—we of this company have not far to seek him—has imagined to be the comment of Aristotle, could he have surveyed some of the aspects of our modern work in biology. "My teaching that the essence of a living being is not what it is made of, or what it does, but why it does it, has been rendered by one of your contemporaries into the statement that life is the continuous adjustment between internal relations and external relations. If this is true, is not the biology which restricts itself to the physical basis and forgets the external world, like your play of 'Hamlet' without the Hamlet? Is not the biological laboratory which leaves out the ocean and the mountains and meadows a monstrous absurdity? Was not the greatest scientific generalization of your times reached independently by two men who were eminent in their familiarity with living things in their homes?" I for one agree with the author of these words that such a comment would be good common sense and therefore good science.

EDMUND B. WILSON.

SCIENTIFIC BOOKS.

Report of the United States Commission of Fish and Fisheries. Part XXV., 1899. By GEORGE M. BOWERS, Commissioner. Washington, Government Printing Office. Pp. clxiii + 397. Plates XXIX + 21.

The contents of this the twenty-fifth report is divided into two portions, of which the first relates to the official and more practical work of the fiscal year, and the second to the special or more scientific work, the preparation of which may have extended over a considerable period.

In speaking of the general condition of the fishery industry, Commissioner Bowers states that the approximate value of the commercial fisheries of the United States in 1899 was $40,000,000, to which the oyster industry contributed about $14,000,000. In comparing the productiveness of the oyster beds of Chesapeake Bay and of Long Island Sound, Commissioner Bowers states that the natural supply of oysters is being exhausted, but that the areas of the sea bottom that are being artificially cultivated are becoming more and more productive. There is sufficient evidence that the increased abundance of cod, in the inshore waters of the New England States, is due to the work of artificial propagation carried on at Gloucester and at Woods Holl. Efforts are being made to rehabilitate the lobster fishery and to devise methods for increasing the number of sturgeon.

Under the direction of Dr. Hugh M. Smith, the Department of Scientific Inquiry has inaugurated or continued several important lines of investigation. The systematic survey of the physical and biological conditions of Lake Erie, begun in 1898 by Professor Reighard, has been continued. Dr. B. W. Evermann has made a biological survey of the waters of the Northwest; Dr. W. C. Kendall has continued his work on the fauna of the lake systems of Maine; and Dr. H. F. Moore has made a study of the physical conditions of Great Salt Lake, and has showed its absolute unfitness for maintaining any form of marine life.

The laboratories at Woods Holl and at Put-in-Bay have been occupied by an enthusiastic corps of investigators, and a building was rented at Beaufort, N. C., to serve as a temporary lab-

oratory. But with these matters readers of SCIENCE are well acquainted. The list of publications for the year numbers forty-six.

The work of the division under Mr. W. deC. Ravenel was the most extensive in the history of the Commission. More than one billion fry were distributed. Mr. Ravenel's report is illustrated with many photographic reproductions and plans of the twenty-nine stations. Mr. C. H. Townsend's statistical tables will prove of inestimable value to those who in the future may wish to follow the rise and decline of the different fisheries. The capture of one hundred and forty bowhead whales by the Pacific fleet in the Arctic Ocean produced an eventful, even if only temporary, elevation in the curve of decline of the whale fishery. It is with a feeling of sorrow that one reads of the slaughter of four thousand sea elephants on Kerguelen Island.

The articles published in the appendix are of both general and scientific interest. Several have a tropical flavor. The papers of Mr. W. A. Wilcox, Mr. C. H. Townsend and Mr. J. N. Cobb are mainly economic. Messrs. Evermann and Kendall have prepared an acceptable check list of the fishes of Florida. New genera and species of fishes from Porto Rico are described by Messrs. Evermann and Marsh. Dr. Moore gives an interesting account of his 'Inquiry into the Feasibility of Introducing Useful Marine Animals into the Waters of Great Salt Lake,' and Dr. Rathbun contributes 'A Review of the Fisheries in the Contiguous Waters of the State of Washington and British Columbia.' The scope of this paper is limited to the fishery questions of the region that are of international concern. While such papers have an immediate interest, their value really increases as time goes on, for they give a record of the more primitive biological conditions, without which it would be quite impossible in the future to determine the changes that have been wrought in the natural productiveness of a region by the occupancy of man.

H. C. BUMPUS.

Report on the International Cloud Observations. Prepared under direction of WILLIS L. MOORE, Chief of Weather Bureau, by FRANK H. BIGELOW, Professor of Meteorology. U. S. Department of Agriculture, Weather Bureau. Report of the Chief of the Weather Bureau for 1898–99. Vol. II. 4to. Washington, D. C. 1900. Pp. 787. Charts 79.

The Report on the International Cloud Observations, just published by the Weather Bureau, is one of the most detailed and elaborate studies of clouds that has yet been issued. Professor Bigelow, who has been in charge of the reduction of the observations, has not limited his investigations to the tabulation and simple discussion of the heights, velocities, and directions of movement of the different clouds, but has gone far into the thermodynamic and hydrodynamic problems which grew out of his study of the cloud observations. As he himself says in his preface: "In order to submit these results to a careful discussion, it has been necessary to prosecute a critical comparative study of several important theories heretofore proposed by meteorologists, so that comparison between observations and theoretical computations can be suitably carried out. Accordingly, a standard mathematical system has been constructed, including in a definite notation the constants, the thermodynamic and the hydrodynamic formulæ pertaining to the atmospheric physical processes and motions, by means of which the work of the several authorities can be reduced to one set of typical equations. The theories of the American and German schools of meteorology have been contrasted, and the results derived from them have been compared with the facts obtained from these cloud observations." This quotation may serve to give some idea as to the thoroughness with which Professor Bigelow has done his work. Indeed, the report is the most comprehensive and important of the Government meteorological publications of recent years.

There are in all fourteen chapters, the first two of which relate to the methods of taking the observations, and of computing the heights, directions and velocities. Chapters 3 to 7 contain summaries of all the observations made with nephoscopes and theodolites, and the discussions of these observations. The subjects treated in the last seven chapters are as follows: 'The Typical Local Circulations over the United States,' 'Diurnal Oscillations of the Barometric

Pressure in Relation to the Diurnal Winds,' 'A System of Fundamental Constants and Formulæ and Reduction Tables,' 'The Theory of Cyclones and Anticyclones,' 'Discussion of the Cumulus and Cumulo-Nimbus Clouds,' 'Reduction of the Pressure and Temperature Maps at Sea-level, 3,500-foot Level, and 10,000-foot Level,' 'The Amount of Heat that would Convert an Adiabatic Atmosphere into the State Actually Existing.'

The reading of this report cannot be lightly undertaken. Indeed, the very completeness of it and the elaborate mathematical discussions which find a place in it, will undoubtedly prevent many persons from attempting to find out what the volume really contains. We do not wish to be understood as saying that work of the sort that Professor Bigelow has here given us is unimportant, or out of place in a thorough study of the observations with which he has had to deal. Far from it. But we cannot help feeling, and feeling strongly, that the observers of the Weather Bureau, both regular and voluntary, and the public generally, should have the chief results of the international cloud observations in this country put before them in a simple, compact form. We hope that the chief of the Weather Bureau may look at this matter in the same light, and may perhaps sanction the publication of a Weather Bureau *Bulletin*, of say 100 pages, in which the results of Professor Bigelow's painstaking research, which are of most general interest, may be set forth.

Professor Bigelow is to be congratulated on the completion of this report, which stands on a far higher plane than most of the meteorological work published in this country.

R. DeC. Ward.

Plane Trigonometry. By Daniel A. Murray, Ph.D., Instructor in Mathematics in Cornell University. New York, London and Bombay, Longmans, Green & Co. 1899. Pp. xiii + 301.

The author has aimed to 'avoid the extremes of expansion and brevity.' Only such topics are fully treated as make up the usual course in plane trigonometry. The thickness of the volume is largely due to the presence of an appendix of historical and other notes, a long list of exercises for practice and review, a table of answers, a four-place and a five-place table of logarithms of numbers, a five-place table of logarithms of the sine, cosine, tangent and cotangent, a four-place table of logarithms (augmented) of trigonometric functions, and a four-place table of values of trigonometric functions. These components constitute little less than half of the book. The other and larger half contains an unusually full exposition of principles. The composition is throughout careful and scholarly. While acquiring a knowledge of the elements as here presented, the student can hardly fail to become aware of the larger aspects of the science.

As regards arrangement and disposition of matter, there is, of course, always room for difference of opinion. Doubtless many teachers would for example prefer to have the notion of the radian introduced at an earlier stage; and there are not wanting reasons of some weight for preferring to present the general ratio definitions of the functions in connection with the conventional system of coordinate axes boldly in the *beginning*, instead of reserving this most commanding point of view, as is here done, for so advanced a stage as Chapter V. However, in things pedagogical, *quot homines, tot sententiæ.*

It remains to say that while paper and typography are good, the book deserves to be more substantially bound.

SCIENTIFIC JOURNALS AND ARTICLES.

The *Journal of the American Chemical Society* for December contains the following articles: 'The Production of Alloys of Tungsten and of

Molybdenum in the Electric Furnace,' Charles L. Sargent; 'A Method for the Rapid Determination of Carbon in Steel,' Robert Job and Charles T. Davies; 'Determination of Iron in Magnetite Ore by the Specific Gravity Test,' Joseph W. Richards; 'Irregular Distribution of Sulphur in Pig Iron,' Randolph Bolling; 'The Composition and Analysis of London Purple,' J. K. Haywood; 'Detection of Foreign Coloring-matter in Spirits,' C. A. Crampton and F. D. Simons; 'A Rapid Method for the Detection of Aniline Orange in Milk,' Hermann C. Lythgoe.

THE December number (Volume 7, Number 3) of the *Bulletin of the American Mathematical Society* contains: 'Report of the October meet- of the Society,' by the secretary, 'On Linear Dependence of Functions of One Variable,' by M. Bôcher; 'Report on Groups of an Infinite Order,' by G. A. Miller; 'A Review of Ewing's Strength of Materials,' by Dr. Chas. Chree; 'A Review of Scheffer's Differential Geometry,' by J. M. Page; 'Notes'; 'New Publications.'

Popular Astronomy for January opens with an illustrated article by Miss Caroline E. Furness on the new 'Photographic Catalogue of North Polar Stars,' which has just been published from Vassar College Observatory. Professor Kurt Laves continues his discussion of the 'Adjustment of the Equatorial Telescope,' and Charles P. Howard his account of the 'Total Solar Eclipse.' Professor Francis E. Nipher's 'Positive Photography with special reference to Eclipse Work' is timely. Professor Herbert A. Howe, director of Chamberlin Observatory, of University Park, Colorado, begins his series of articles on astronomical books for the use of students. Professor Asaph Hall contributes a note on multiplication showing some peculiarly symmetrical results. The department of Astronomical Phenomena announces the eclipses of the coming year, and gives much space to news of comets, asteroids, etc. The number includes the usual general, spectroscopic and variable star notes, and W. W. Payne's second article on 'The Figure and the Attraction of the Earth.'

Nature announces that the Anthropological Institute will issue an anthropological journal to be entitled *Man*, which will appear monthly. Special attention will be given to the data concerning the origin of those forms of civilization which have become dominant.

SOCIETIES AND ACADEMIES.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 330th meeting was held on Saturday evening, December 15th.

F. A. Lucas exhibited the under portion of the skull of a large specimen of the gar pike, *Lepisosteus tristoechus*, showing fracture and repair of the sphenoid. He stated that this was a good example of the fact that many animals could successfully recover from very severe injuries, since in the present case the breaking of the sphenoid must have entailed severe injury to and deflection of the entire cranium, and yet recovery had taken place.

C. W. Stiles spoke of 'Some Tropical Parasites that may be introduced by our Returning Troops,' saying that the present conditions in China where troops were gathered from many parts of the world were particularly favorable for the interchange of parasites that were ordinarily confined to certain areas. The conditions in Manila were also favorable for attacks of parasites and their subsequent introduction into this country. The speaker described the various species of parasites that might be met with, their structure, mode of reproduction, the manner in which they entered the system and their effect upon it, illustrating his remarks by diagrams. But one or two of these species it was pointed out, were really to be apprehended, and as most of them were taken through the medium of drinking water, the danger could be almost entirely obviated by boiling the water.

E. W. Nelson presented a paper on 'The Caribbean Seal,' saying that while this was the first seal met with by the early explorers of the New World, and was an animal of considerable size and former extensive distribution, it was one of the least known of North American mammals and not accurately described until 1884. The various accounts of this seal, from the time of its discovery by the sailors of Columbus up to the present time were briefly no-

ted, the speaker then describing the habits of the animal as observed by him during a recent visit to the Triangles, in the Gulf of Campeche, to which the seal now appears to be restricted. They were sluggish and stupid, making practically no defense when attacked, and very easy to approach. While on shore they commonly laid on their backs, basking in the sun for hours, although the heat was so intense that iron exposed to the sun became too hot to handle with comfort, and dead seals soon had the epidermis so heated that the hair slipped off. Owing to the killing of these seals for oil, sold for lubricating purposes, their numbers had been greatly reduced, it being estimated that under one hundred were now living so that the extinction of the species would probably soon take place.

F. A. LUCAS.

TORREY BOTANICAL CLUB.

THE scientific program on November 28th consisted of a paper, soon to be printed, by Mr. Frederick H. Blodgett, on 'The Seed and Seedling of *Lilium tenuifolium* Fisch,' in which the seed characters were presented in detail, and with comparisons with those of *Erythronium*. Interesting differences were found in the size of the *Lilium* seeds about 93 per cent. of which germinated the small seeds as quickly as the larger, though with less vigorous subsequent growth.

On Tuesday afternoon, December 11th, the Club met at the Botanical Garden at Bronx Park. The program included a brief address by Professor Charles E. Bessey, a visit to the Garden conservatories with explanations by Dr. Britton, and the exhibition by Miss Anna M. Vail of valuable books recently added to the Garden library. Mr. R. M. Harper exhibited a very interesting series of specimens and photographs of plants from Georgia, and gave notes on their habitat and distribution. Dr. J. K. Small described a series of tree and shrub specimens from the south, with critical notes. Dr. D. T. MacDougal presented notes on the bulbils of *Lysimachia terrestris*. These bulbils are formed during the latter part of the season, in the axils of many leaves, and are morphologically branches. On completing their growth they pass into rhizomes. They are killed by freezing and desiccation.

Another paper was by Dr. M. A. Howe, 'Remarks on rare North American Hepaticæ.' The first hepatic discussed was *Riccia Beyrichiana*, a species which was discovered about seventy years ago 'between Jefferson and Gainesville, North America,' by the German traveller Beyrich, but which has of late been a subject of considerable doubt, inasmuch as it has not been seen since. Now, however, it has apparently been rediscovered by Mr. R. M. Harper, who found it during the last summer at Athens, Georgia, scarcely more than twenty miles from the locality where it was evidently first collected.

Dr. Howe also furnished a brief account of a collection of Hepaticæ made in the Yukon region by Mr. R. S. Williams—a collection of much interest, inasmuch as it contained one species which appears to be entirely new, one which has not heretofore been reported from this continent, five others new to the Alaskan region, and, besides these, two or three which have been rarely collected in America. The report on Mr. Williams's Hepaticæ is soon to be published.

EDWARD S. BURGESS,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of the Academy of Science of St. Louis of December 3, 1900, fifteen persons being present, Mr. William H. Roever, of Washington University, read a paper on 'Brilliant Points and Loci of Brilliant Points.' The paper gave the analytical conditions which define the brilliant point of a surface, the brilliant point of a space curve, the brilliant point of a plane curve and the brilliant point in space of two dimensions, when the source of light is such that the incident rays are normal to a given surface and the recipient is such that the reflected rays are normal to another given surface. Formulæ were given for the important special case in which the source and recipient are points. The paper also contained a general method for finding the equation of the locus of the brilliant points of a moving or variable surface or curve, together with a number of applications. Such loci may often be perceived when an illuminated

polished surface is rapidly moved, as when a wheel with a polished spoke is rapidly rotated. Another interesting example in loci of brilliant points is that of a circular saw which has been polished with emery in a lathe and thus received a great number of concentric circular scratches. The locus of the brilliant points of this family of scratches was shown in this paper to be a curve of the fourth degree. In the special case when the point source of light and the eye of the observer (the point recipient) are in a plane through the axis of the saw, the curve degenerates into a circle and two coincident straight lines. A photograph of the saw curve has been taken in which the optical center of the camera lens is the point recipient. Other interesting facts and a number of geometrical constructions were also given in this paper.

Three persons were elected to active membership in the Academy.

William Trelease,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

THE ELECTRICAL THEORY OF GRAVITATION.

It is, perhaps, by the severe but impartial criticism of his work that the greatest of all possible obligations is laid upon the scientific investigator, for thereby his theories are purged of what may be incorrect or trivial, and that part of them which may be true is compacted and separated from what might otherwise hide its value, and cause it to be neglected.

Unfortunately I have been unable to profit as much as I felt I had a right to expect from Dr. Franklin's letter, Science, December 7th, as he has apparently been unable to find time for that careful examination and study which the subject, aside from the paper, demands. It is a matter of regret, also, in view of Dr. Franklin's admirable qualifications for dealing with the question, that he should have directed his criticism, in every single case, against theories which are the exact opposite of those which I hold, and which I have explicitly set forth in the paper referred to.

But though Dr. Franklin has with some slight lack of courtesy invited his readers to 'ignore' my remarks on the methods by which my theory was deduced, I shall not return the compliment by 'ignoring' his criticism, because it contains a number of very serious misstatements which should be promptly pointed out, as otherwise they may become sources of error.

To consider, first, his criticism of my paper, he says (par. 1):

"Professor Fessenden in a recent number of Science discusses the nature and velocity of gravitation. There is, no doubt, something of value in Professor Fessenden's suggestions and much that is new. However, the explanation of gravitation which Professor Fessenden offers is by no means so adequate as would appear from Professor Fessenden's discussion."

On careful perusal we find his reasons for making this statement to be three in number. In regard to the first he says:

"If we admit that the diminution of volume of the ether at each point is proportional to the resultant intensity of the electric field, then the part of the energy which depends upon diminution of volume cannot be separated in its effects from the part of the energy which depends upon the shearing distortion, inasmuch as both are proportional to the square of the resultant field intensity. Therefore a diminution of volume of the ether could not explain gravitation, but would only be involved in the explanation of ordinary electrical attraction and repulsion."

But, *so far from my theory implying a diminution of the density of the ether at each point proportional to the resultant field intensity, F, I have expressly stated that the change of density is proportional to F^2*, as witness the following extracts from my paper:

"Whilst the one which is a density must decrease with the *second* power of the corresponding intensity."

"And hence, as my experiments prove, the change in density is proportional to the *square* of the electric intensity."

As a matter of fact, even a cursory examination of my paper will show that the whole point of my argument rests on the fact that it is the second and not the first power which is involved. For the qualitative equation is

$$M/L^3 = T^2/L^2 \times M/LT^2,$$

i. e., density varies with the inverse square of voltivity and directly as compressibility.

Since, then, my theory calls for a change in density proportional to F^2 and since compressional energy varies as the second power of the compression, my theory makes the compressional energy vary as the fourth power of the electric intensity.

Dr. Franklin later says (last par.):

"If, however, the compressional energy were proportional to the fourth power of the resultant field intensity, then * * * gravitation would be provisionally explained."

Out of Dr. Franklin's own mouth, therefore, we have it that my theory provisionally explains gravitation.

As regards the second point, he says:

"Professor Fessenden, in his article referred to, speaks quite in general of the compression of the ether near a charged body, or ion, without localizing the distortion."

But this is not true. I have given the precise and exact distribution, par. 40, where I state, "This change in density varies as the fourth power of the distance from the corpuscle."

I do not wish to complain, but no one cares to be continually misrepresented, and it is much to be regretted that Dr. Franklin was not able to note that I had covered the points he has criticised.

Thirdly, Dr. Franklin says (p. 889, 1st col. bottom):

"One might therefore expect that an hypothesis as to the constitution of matter which clears up the nature of inertia, even provisionally, would throw some light upon the nature of gravitation, but it does not seem to be so, and Professor Fessenden must needs say more from his point of view before we will be convinced."

But this is just what my theory *does* do. As I have pointed out elsewhere this is one of the very strongest points in favor of my theory, and in the paper criticised I have explicitly stated this, as, to quote (par. 41):

"The inertia of the atom is due to the electromagnetic inductance of the corpuscular charge, and gravity is due to the change of density of the ether surrounding the corpuscles, produced by the electrostatic stress of the corpuscular charge. *Mass and gravity thus bear a constant ratio.*"

Having thus answered all of Dr. Franklin's objections to my theory, I must now call attention to some very serious misstatements.

To take the first one. He says (p. 887, par. 2):

"Professor Fessenden claims to have derived *numerical functional relations* [the italics are Professor Franklin's] with the aid of his Qualitative Mathematics."

Now it is very wrong to say this. If I were to write an article in a scientific paper, stating that Dr. Franklin believed that the earth was flat, and after stating that this was believed by scientists to be impossible, 'on definite rational grounds,' and inviting my readers 'to ignore' his arguments, Dr. Franklin would justly consider that he had reason for complaint. But he would not have so much of reason as I have, for whilst Dr. Franklin has never, to my knowledge, published his opinions on this matter, I have, in no less than four papers, *explicitly stated views which are the exact reverse of those Dr. Franklin attributes to me.* In the very paper he is criticising I say (par. 5):

"Qualitative Mathematics, as its name signifies, is used, *not for the exact determination of numerical values*, but for the prediction and classification of phenomena."

I really could not put it any plainer. I do not see why Dr. Franklin makes his statement. He cannot point to *any* statement or *any* work which I have ever done in which I have tried to deduce numerical relations by means of qualitative mathematics.

So far from this being the case, I have frequently stated exactly the opposite. As instance the above quotation. Also in my paper on the 'Nature of Electricity and Magnetism,' *Phys. Rev.*, Jan., 1900. Also, in my paper in the *Electrical World*, of some years ago, I point out very specifically that this same numeral coefficient, which Dr. Franklin says I have overlooked, cannot be determined by Qualitative Mathematics, and I then go on to point out that since, this coefficient being of zero quality, we can always make it equal to unity by choosing suitable units, it is a matter of no consequence in discussing the *nature* of phenomena, however important it is as regards

the *quantity* of the action. *Thus, so far from overlooking it, I called attention to it, no less than four years before Lord Rayleigh did, in the article of his which Dr. Franklin quotes.*

So much for my theory. As regards my practice, one has only to read any of the papers in which I have used this method to see that I have never used other than experimental means to determine this unknown coefficient of zero dimensions. For example, in my paper on the nature of electricity, I first show that specific inductive capacity k is a density, and I then find, *by experiment*, what numeric k must be multiplied by to get the actual value of that density. Similarly, in the same paper, having shown that the magnetic coefficient a has the quality of hysteresis, I then proceeded, *by experimental means*, to find what the numerical relation between the two is.

A second misstatement is the following (p. 888, par. 4):

"Maxwell showed that the mechanical stresses in the dielectric tend to produce a diminution of volume."

There are no less than three mistakes in these lines. In the first place Maxwell never showed anything of the kind, and Dr. Franklin cannot refer to any passage in his writings where any change of volume, due to the electrically produced dielectric stresses is even hinted at. Second, the Maxwell stresses are incapable, as has been pointed out by several eminent physicists, of giving any diminution in volume, except on making assumptions not contained in Maxwell's theory or in his writings. Thirdly, the change in volume is not a diminution, but in the most general case an expansion, and only under certain conditions does it become a diminution.

Quinke had previously worked along that line, and found that some dielectrics expanded and others contracted, but did not give the law of the change. It was not until I had shown that contracting dielectrics behaved as negative uniaxial crystals in Kerr's phenomena, and did not obey the Maxwellian law, $1/\sqrt{k\mu}=$ velocity of light, whilst expanding dielectrics behaved as positive crystals and did obey that law; also that the compression depended upon the square of the electric intensity and the compressibility, and that mixtures and ionized compounds contracted whilst pure dielectrics expanded, that the phenomenon was exactly formulated, by me, as follows:

"All simple non-ionized dielectrics expand under electric stress, the change in volume being proportional to the square of the electric intensity, and inversely as the compressibility; they act as positive uniaxial crystals in Kerr's phenomenon, and obey Maxwell's law for the refractive index."

On p. 888, par. 2, he says:

"Physicists have known for many years" that attraction is to be attributed to ether energy, which decreases as the bodies approach each other."

Has this statement any basis of fact? Can Dr. Franklin adduce a particle of evidence to show that Hick's bubble theory, as developed by McAulay, or Newton's, or that theory of Bjerknes's which Larmor seems to regard with some favor, is more probable than the old corpuscular one (of le Sage? I write away from my books). As a matter of fact, can Dr. Franklin refer to the slightest evidence that ether is necessary to transmit gravitational force? And if Kelvin's value for the ether constants were correct, would this not be very improbable? And had it ever been shown that the ether has the properties requisite to do it, before I showed it, a couple of years ago?

Still one more point, and I mention this because I think Dr. Franklin has been a little unfair. In writing of the electrical theories of matter, he does it in such a way, no doubt unintentionally, as to convey the impression that the theories I have advanced are not original with me, but form a part of the common scientific stock of knowledge. For instance, in speaking of the 'electrical hypothesis of the constitution of matter.'

But it was the writer who first introduced the idea of the universal association of the electrical charge with matter. I believe that it is a fact that Dr. Franklin cannot refer to a single sentence in all scientific literature in which this theory was put forward, still less any proof given, prior to my papers of 1891 and 1892 in the *Electrical World* and SCIENCE, with their contained proofs. Prior to that date the ionic

charge had never been considered in connection with the atom save in relation to chemical and molecular effects.

The last statement I shall criticise is the following: He says (p. 888, 3d par.):

"It is now pretty well established that the ether energy having to do with electrical attraction and repulsion is dependent upon a sort of *shearing distortion* of the ether unaccompanied by any sensible diminution of volume, that this ether distortion is what is known as *electric field*, that the propagation of this energy constitutes *electrical waves*, and that the movement of the ether which comes into play during the establishment of this shearing distortion, or which comes into play while distortion at one place is relieved and distortion at a contiguous place is built up, is what is known as *magnetic field*."

Surely not!! So far from being established, Dr. Franklin cannot adduce the slightest particle of evidence for it. Though Maxwell and Lodge have used this theory, yet both Lord Kelvin and Professor J. J. Thomson have suggested exactly the opposite theory, and Heaviside has pointed out (Electromagnetic Theory, Vol. 1), that the theory which Dr. Franklin states is 'pretty well established' is at present as hard to reconcile with the facts as the other theory, so that the weight of authority would appear to be fairly evenly divided. And one of our greatest living physicists, J. J. Thomson, uses the opposite theory, of late exclusively. Moreover I have elsewhere pointed out that the variation of μ with the first power and of k with the second power is conclusive proof that the opposite theory is true.* If we chose to be unconvinced by this, then there is not the slightest evidence one way or another, and Dr. Franklin can add considerably to his already brilliant reputation by producing some evidence in favor of his statement.

REGINALD A. FESSENDEN.

* Those who are acquainted with my work on the nature of electricity and magnetism may remember that the proof that magnetism was a shear was based upon the following:

(a) The determination of the fact that either k or μ must be a density, thus confirming Williams's result.

(b) The demonstration of the fact that whichever one of the two k or μ is a density, must depend upon the first power of the corresponding force, whilst the other must depend upon the second power of the corresponding force.

(c) The experimental determination of the fact that μ varies with H whilst k varies with F^2.

A second proof was then indicated, depending upon the nature of the Lagrangian terms involved in the change of k and μ in elastic phenomena.

I have now to add a third. Briefly stated it is as follows: Since either k or μ is a density, then either H must be a shearing stress and F a velocity or *vice versa*. It is next shown that in the electric current we have a non-conservative system, and from quite general principles it is shown that it is the non-conservative system which must involve the velocities. And it is shown that under no circumstances could the equation expressing the amount of the I^2R loss be of the form it is if F were a shear, since in that case an operator which experiment shows is attached to an electric term would be connected with a magnetic term instead.

A BIBLIOGRAPHIC CATCH TITLE FOR THE YEARS 1900 to 1999.

IN a note published in SCIENCE, May 11th, I called attention to a bibliographic matter which I wish to return to again.

Some twenty years ago I adopted the plan of placing all bibliographic titles at the end of an article in a single list with authors' names arranged alphabetically and each author's papers arranged chronologically. As an essential part of the plan, the citation in the text consisted simply in giving the author's name and the last two figures of the year of publication preceded by an apostrophe. To avoid ambiguity, in case two or more cited papers were published by an author in one year, the abbreviated dates were followed by a lower-case letter used as an exponent. This plan has been kept up since then in the 'Contributions from the Zoological Laboratory at Harvard College.' Owing to its simplicity and the evident advantage which it gives the reader by acquainting him at once with the date of the paper cited, this plan has come into rather common use.

The apostrophe used to mark the omission of the first two figures of the year-date could not be used without ambiguity for dates subsequent to 1899, and I have consequently urged in the note

referred to that the apostrophe should be used to indicate an omitted 18, never an omitted 19. It then occurred to me that a comma might be similarly used to denote the omission of 19; but there seemed to be such important objections to this, that I dismissed the matter without further thought until, a few weeks ago, I received a letter from Mr. R. Pearl of the University of Michigan, in which he urged the desirability of adopting some method of abbreviation, and suggested the use of a period. There are, however, quite as serious objections to a period as to a comma. After some correspondence on the matter it has seemed to both of us that the *colon* so used would afford the best solution to the problem; but in order to avail ourselves of other possible suggestions, we desire to call attention to the matter in SCIENCE.

The signs hitherto considered and some of the more obvious objections to them are the following: The *comma* would be objectionable because in almost every citation two commas—one for punctuation, the other to mark the elision—would be brought together, and no proof-reader could be expected to accustom himself to the anomaly; thus in a recent publication, if the dates had been 1993, etc., instead of 1893, etc., the use of the comma would have given this undesirable result: "In Anurida, as in Orthoptera (Wheeler, ,93; Heymons, ,95[b]) and Lepisma (Heymons, ,97[a]), etc." The *period* is so commonly used as a decimal point, that .93 or .97[a], for example, would be misleading. It would clearly be of some advantage to have a character that should stand, like the apostrophe, on a line with the tops of the figures; but the various signs which usually have that position, as the asterisk, obelisk, etc., have such a fixed usage, as a means of referring to footnotes, that it seems unwise to employ any of them for this purpose. An *inverted period* would be open to the objection that a defective apostrophe could not be distinguished from it. The *dash* takes up too much room; the *hyphen*, though shorter, is not better in this respect than the colon, and has the disadvantage that, in the case of papers occupying more than a single year in publication, it now has to serve for omitted digits which might, or might not, be the figures 19, for which we should wish it invariably to stand.

So far as I recall, there is only one usage, except that of ordinary punctuation, to which the colon has been put that would be liable to interfere with its use for the purpose contemplated here. It has been used to separate the number designating a volume from that designating the first page of an article in that volume—a substitute for the letter *p*. Since in the proposed usage the colon would stand between the name of the author cited (not a number) and the last two figures of the year in which his paper was published, I think no ambiguity could arise. If, however, serious objections to the use the colon, or a better plan, occurs to any one interested in the matter, both Mr. Pearl and the writer would be glad to profit by suggestions communicated through SCIENCE or directly. E. L. MARK.

HARVARD UNIVERSITY,
December 13, 1900.

ASTRONOMISCHER JAHRESBERICHT.

EACH year there is being issued under the editorship of Professor Dr. W. Wislicenus, from the press of Georg Reimer, an Astronomischer Jahresbericht, or annual review of all kinds of *astronomical publications*, including writings on geodesy and navigation if not too remotely connected with astronomy. This work is carried on under the supervision of the Astronomische Gesellschaft. The first volume contains the publications of 1899, and consists of xxiv + 537 pages, 8vo. This was issued in the spring of 1900.

In the interests of publishers, of readers and of the nation which he represents, the associate-editor for the United States desires to make the compilation and review of American publications on the above named subjects as complete as possible. To this end he invites authors and publishers to favor him with the title and place of publication of each book or article issued during 1901 and each subsequent year or a copy of the same if convenient that it may be reviewed for this purpose. The reviews are merely explanatory—not critical.

HERMAN S. DAVIS.

INTERNATIONAL LATITUDE OBSERVATORY
GAITHERSBURG, MARYLAND.

DIFFRACTION GRATINGS FOR GRATUITOUS DISTRIBUTION.

TO THE EDITOR OF SCIENCE: Two or three years ago while engaged in some experimental work on the reproduction of diffraction gratings by photography, I devised a method of copying a Rowland 14,000 line to the inch grating, and silvering the copy, transforming it into a reflecting grating. The original was an excellent glass grating kindly loaned to us by the Johns Hopkins University. I was unable to get satisfactory copies with the bichromated gelatine but succeeded very well with albumin. I found this difficulty, however. To reproduce so fine a spacing it was necessary to use an exceedingly thin film, so thin, in fact, that the retardation of the light waves in traversing the 'bars' was insufficient to give spectra of any brilliancy. By thickening the film I was able to get a brilliant grating occasionally, but usually the lines ran together. It then occurred to me to silver the gratings, for the retardation by reflection is four times the retardation by transmission. The thin film failures, which I had thrown into a drawer as scrap plate-glass, were accordingly immersed in a chemical silvering solution, and when washed and dried were found to give brilliant spectra. One of these was exhibited by Professor Boys at a conversazione of the Royal Society about two years ago. Having about thirty of these gratings, which, while not as perfect as an original Rowland grating, being made on ordinary plate glass, are nevertheless suited for the ordinary purposes of the laboratory, I am desirous of placing them where they will do the most good. There must be among our many universities some physical laboratories which are not fortunate enough to have a good diffraction grating. I shall be very glad to distribute these copies to laboratories desiring them, as long as the supply holds out. I shall be glad if applicants will state whether the laboratory possesses a good spectrometer, and also the number of students engaged in the pursuit of physics. Some of the gratings are very good indeed, others quite poor as to general appearance, but all will give tolerably good spectra, and can be used for wave-length determinations. They will show the nickel line between the sodium lines in the solar spectrum very distinctly. Applications from high-schools will not be considered. Failure to receive any reply must be taken as evidence that the supply has been exhausted.

R. W. WOOD.

UNIVERSITY OF WISCONSIN.

NOTES ON INORGANIC CHEMISTRY.

ARGON AND ITS COMPANIONS.

ON November 15 a paper was read before the Royal Society by Professor William Ramsay and Dr. Morris W. Travers on 'Argon and its Companions,' which was a continuation of the previous papers of the same authors on the inert gases of the atmosphere. In the early summer of 1898 the discovery of neon and krypton was announced, and later a heavier atmospheric gas was found, to which the name xenon was given. At that time krypton and xenon were not obtained in a condition pure enough for the investigation of their physical constants.

The present paper deals chiefly with these three gases, which have been isolated and studied. By the evaporation of a large amount of liquid air a mixture of argon, krypton and xenon was obtained, the former largely predominating. This mixture was liquefied by liquid air and the three separated by fractional distillation, many times repeated. At the temperature of boiling air krypton has considerable vapor-tension, while that of xenon is scarcely appreciable. Neon was isolated from the first portion of gas escaping from boiling air. This consisted chiefly of nitrogen, which was then liquefied and a part of the liquid evaporated by passing through it a current of air. This gas, after the removal of the oxygen by hot copper, contained most of the helium and neon present in the air. After purification from nitrogen in the usual manner, the helium and neon were separated from the argon present by fractional distillation. To separate these gases was very difficult, but was finally accomplished by condensing the neon by means of boiling hydrogen. In this way pure neon was obtained.

A determination of the ratio of the specific heats of these gases showed that they are all monatomic. A number of the physical prop-

erties of these gases were determined, which are given in the following table:

	Helium.	Neon.	Argon.	Krypton	Xenon.
Refractivities (Air 1)	0.1238	0.2345	0.968	1.449	2.364
Densities of gases (O=16)	1.98	9.97	19.96	40.88	64
Boiling points at 760 mm	?	?	86.9° abs.	121.33° abs.	163.9° abs.
Critical temperatures	?	Below 68° abs.	155.6° abs.	210.5° abs.	287.7° abs.
Critical pressures	?	?	40.2 m.	41.24 m.	43.5 meters.
Vapor-pressure ratio	?	?	0.0350	0.0467	0.0675
Weight of 1 cc. of liquid.	?	?	1.212 gms.	2.155 gms.	3.52 gms.
Molecular volume	?	?	32.92	37.84	36.40

In the vacuum tube neon is extremely brilliant and of an orange-pink hue, and is characterized by multitude of intense orange and yellow lines; krypton is pale violet, and xenon is sky-blue.

The five elements clearly form a series in the periodic table, between the seventh and the first groups, that is, as a transition from the most negative to the most positive group. This is of the greatest interest, since in two recently published papers Ladenburg has given the atomic weight of krypton as about 59, placing the element between nickel and copper. It could thus find no place in the periodic table, as it is now understood. On the other hand, as determined by Ramsay and Travers, the elements find a natural place in the eighth group, as a transition from the negative series of the seventh group to the positive series of the first group.

J. L. H.

THE RESIGNATION OF PRESIDENT MENDENHALL.

MEN of science everywhere will learn with deep regret that Dr. Thomas C. Mendenhall has been compelled by ill health to resign the presidency of the Worcester Polytechnic Institute. Fortunately President Mendenhall's health has only been injured by the great amount and responsible character of the work he has undertaken, and there is every reason to believe that after rest in Europe he will return prepared to continue work as important as that which he has already accomplished at the Ohio State University, the Imperial University of Japan, the U. S. Signal Service, the Rose Polytechnic Institute, the U. S. Coast and Geodetic Survey and the Worcester Polytechnic Institute. It is known to all men of science that, while occupying executive positions of great responsibility, President Mendenhall has carried out scientific researches of the utmost importance, and has taken an active part in all movements for the advancement and diffusion of science in the United States. He is one of the most efficient members of the National Academy of Sciences and of the American Association for the Advancement of Science, of which he has been president. He is now president of the American Metrological Society, chairman of the Massachusetts Highway Commission and a leader in many important scientific movements. As one of the editors of this journal since its reorganization six years ago his services have been invaluable. The grounds of President Mendenhall's resignation, the reluctance with which it was accepted and the great value of his work at the Worcester Polytechnic Institute is shown by the following letters. The letter of resignation, dated October 15, 1900, is as follows:

Hon. Stephen Salisbury,
President, Board of Trustees.
Worcester Polytechnic Institute:

Dear Sir:

I hereby tender my resignation as president of the Worcester Polytechnic Institute, to take effect on the first of July next.

I send this communication so long in advance in order to afford ample time for the selection of a suitable person to fill my place, and I hope I may be allowed to add a few words in acknowledgment of the continued and unvarying kindness which the board of trustees have shown me during my connection with the institute.

As far as I can now remember every suggestion I have made relating to the management of the institute has been approved by the board and every plan for its betterment that I have submitted has received its cordial, unanimous and hearty support. My personal relations with the members of the board have been, without exception, agreeable; everything that they could do to make my administration successful and my life in Worcester pleasant has been done, and I cannot give measure, however much I might multiply words, to the feelings of appreciation and grati-

tude with which I must always regard their considerate treatment of me during my term of service.

Naturally it is with great regret that I look forward to the early breaking off of a relation which has been to me so satisfactory. During the past year the condition of my health has been such as to cause much anxiety and this has been increasingly so during the past few months. The conclusion has been forced upon me that I must indulge myself in a long vacation or period of rest as free as may be from care and responsibility, too long to be for a moment considered compatible with a continuance of my connection with the institute. While thus compelled to sever this connection, there is no small consolation in the fact that I leave the institution at a period which may fairly be called the most prosperous in its history. Its numerical strength has not before been equalled; its next graduating class will be larger than any that has preceded it; its material equipment in the way of apparatus, machinery and other appliances for instruction has been greatly increased during the last few years and is now as nearly adequate as that of the best institutions of its class; during the same time new departments have been developed and specialization has increased; its internal affairs are directed by a relatively large, able and harmonious corps of instructors, and it is everywhere admitted to be in the front rank of the engineering schools of the country. Whatever progress towards this end has taken place during my administration, I wish to attribute to the generous support of the board of trustees, the cordial and enthusiastic cooperation of the faculty, the earnest and conscientious devotion to work which is and, I think, always has been characteristic of the student body, and, finally, the growing interest of the alumni, now nearly a thousand in number, scattered over the civilized world. The latter has been specially manifest on the organization of a number of new and active Alumni Associations, one of which is now to be found in almost every city of the first importance.

Under the continued fostering care of those who have so generously and unselfishly supported it in the past and with any one whom the board of trustees may select at its head, I shall confidently expect it to maintain its rank among the leading exponents of technical education.

I need hardly say that it will ever be a pleasure to me to further its interests in any way in my power.

I am yours faithfully,

T. C. MENDENHALL.

On December 20th in reply, the following communication was sent to Dr. Mendenhall by the committee on the part of the board of trustees:—

President T. C. Mendenhall, Ph.D., LL.D., Worcester Polytechnic Institute:—

Dear Dr. Mendenhall:

Your letter of October 15, 1900, resigning your office as president of the Worcester Polytechnic Institute, has been received by the trustees with expressions of profound surprise and regret. They deeply deplore the cause which alone necessitates this action on your part. They have been very slow and unwilling to admit the fact. In conference with you and at repeated meetings of the board, they have earnestly sought to find some way by which such a serious loss as your permanent separation from the institute might be averted. They are, however, compelled to recognize that your reasons leave them no option, either as respects your interests or those of the institute, and they therefore reluctantly accept your resignation as president of the institute to take effect, as you request, July 1, 1901.

In thus regretfully acceding to your request, the trustees wish to thank you for your thoughtful consideration of the welfare of the institute in giving them timely notice of your decision, and for the most courteous terms in which you have made it known to them. They also desire to communicate to you and to place on record their high and grateful appreciation of your laborious, devoted and successful service for the institute. During your administration, which in July will cover seven years, the institute has steadily grown in its productive endowment; in the size and value of its plant; in the excellence of all its facilities; and in the number of its faculty, instructors and students. New buildings have been erected and equipped. Large additions have been made to machinery and apparatus. The courses of study have been extended, revised and brought to the highest standards. The success, high rank and deserved fame of the institute have been greatly and solidly increased. All this has, in large measure, been due to your wisdom, faithfulness, tact and unwearying courtesy as president.

Nor would the trustees fail most cordially and thankfully to recognize the distinction which your ability as a scientific man, your skill and charm as a lecturer, and your ready, valuable and public spirited service of the city and the commonwealth, have given to the institute. In all these and similar directions your departure from among us will leave a vacancy not easy to fill. This adds to the pain with which, not only the institute, but also the city and the state, will lament your forced retirement on account of impaired health.

The trustees assure you that they fully reciprocate your expressions of personal esteem and of gratitude for the most amicable relations which have always existed between them and you. They earnestly hope that the rest and relief from responsibility to which you look forward will speedily result in your complete restoration to health and in fitness for increased usefulness and happiness, and to this end their good wishes will always follow you.

We remain, dear Mr. Mendenhall, on behalf of the trustees and with high regard, faithfully yours,

STEPHEN SALISBURY,
DANIEL MERRIMAN,
C. G. WASHBURN,
Committee of Trustees.

THOMAS A. WILLIAMS.

WE learn with much regret of the death of Professor Thomas A. Williams, assistant-chief of the Division of Agrostrology, U. S. Department of Agriculture, and a well known authority on botany and agriculture. He died at his home, near Washington, on December 23d, at the early age of thirty-five years. The high esteem in which Professor Williams was held by his colleagues is expressed in the following resolutions:

It is with feelings of profound sorrow and regret that we, the employees of the Department of Agriculture, learn that death has removed from among us our beloved companion and co-worker, Thomas A. Williams, a classmate and intimate associate of many of our number. His broad knowledge of scientific matters, his keen appreciation of nature, his kind and forbearing disposition has endeared him to all. He was known to his associates as an indefatigable worker and investigator.

Resolved, That in the death of Professor Thomas A. Williams, science and agriculture have suffered a great loss, and we, his associates, a dear friend, whose self-forgetfulness in his kindly consideration for the feelings of others, and uniform cheerfulness, often under conditions of severe physical suffering, revealed a lovable character of the highest Christian type. The loss to the Division of Agrostology is irreparable. In the performance of his official duties he had proved himself an excellent executive and an organizer of unusual merit and his relations with his associates in office were always such as to command the highest esteem and respect. He never shirked a duty, and however difficult the undertaking, the work performed by him was done most creditably. His loss will be felt most keenly by his associates in the division, and his memory will remain with them as one whose exemplary life and steadfastness of purpose they should strive to emulate.

Resolved further, That we tender to his bereaved family our heartfelt sympathy in their great loss and invoke for them the blessing of the Heavenly Father, who alone can heal the broken heart and give lasting comfort.

Resolved, That copies of these resolutions be sent to the family of the deceased and to the various daily and scientific journals.

COMMITTEE ON RESOLUTIONS FOR THE DEPARTMENT OF AGRICULTURE.

WASHINGTON BIOLOGISTS' FIELD CLUB.

WASHINGTON, D. C., December 27, 1900.

Whereas, We have learned with sorrow and a sense of deep personal loss of the sudden death of our fellow-member, Thomas A. Williams.

Resolved, That the Standing Committee of the Washington Biologists' Field Club voices the feeling of every member in paying tribute to the memory of Mr. Williams, whose gentle and kindly disposition, charming good-fellowship and sterling qualities endeared him to every one of us. We recall with pleasant remembrances his interest in the work of the Club and its social relationships, as well as the many delightful hours spent with him in the field. We extend our heartfelt sympathy to Mrs. Williams in this the hour of her great bereavement, which we hope may be lightened by the thought that he passed away in the same peaceful and tranquil spirit in which he had lived.

Resolved, That a copy of this tribute be sent to the family of the deceased, and that it be published in *The Plant World*, of which he was an editor, and in SCIENCE.

By direction Standing Committee,
Washington Biologists' Field Club,
CHARLES LOUIS POLLARD,
Chairman.

THE AMERICAN SOCIETY OF NATURALISTS.

THE Society met at Johns Hopkins University, Baltimore, on the 27th and 28th of December. In addition to serving as a center for the important affiliated societies devoted to the natural sciences, the Society as usual had what may be regarded as two scientific sessions. The address of the president, Professor E. B. Wilson, printed above, was given at the annual banquet on Friday evening, and on Thursday afternoon a discussion, which will also be printed in this Journal, took place, its

subject being 'The Attitude of the State towards Scientific Research,' and the speakers being Professor H. F. Osborn, Dr. L. O. Howard, Professor W. B. Clark, Dr. B. T. Galloway and Professor William T. Sedgwick.

The business transacted by the Society included an appropriation of $50 toward the support of the university table at the Naples Zoological Station, and $50 to support a table at the Marine Biological Laboratory at Woods Holl. It was also voted that a committee of five be appointed by the incoming executive committee to select appointments to the university table at Naples, and to raise, if possible, additional funds for its support. A resolution was passed protesting against the duty on wax and other models intended for scientific research in educational institutions.

The most important business transacted by the Society was the consideration of its relations to the Naturalists meeting simultaneously at Chicago. The action taken was as follows: (1) Section 1, of Article IV, which limited the territory for holding meetings, was striken out of the Constitution and was transferred to the By-Laws. (2) This By-Law was temporarily set aside for the purpose of providing for the meeting of the Society in Chicago in 1901. (3) The Executive Committee was empowered to confer with those interested in the formation of a Western Branch of the Society.

Officers for the ensuing year were elected as follows:

President, Wm. T. Sedgwick; *Vice-Presidents*, L. O. Howard, L. M. Underwood, J. Walter Fewkes; *Secretary*, A. D. Mead; *Treasurer*, M. M. Metcalf; *Executive Committee from Society at Large*, G. H. Parker, J. McK. Cattell.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

A MEETING of the Council of the American Association for the Advancement of Science was held at Johns Hopkins University, Baltimore, at one o'clock on December 28th, with the president of the Association, Professor R. S. Woodward, in the chair. Professor C. S. Minot, the president-elect, was also in attendance.

The permanent secretary, Dr. L. O. Howard, made a report on the affairs of the Association, including the preparations for the meeting next August at Denver. Professor L. G. Carpenter has been in charge of the local arrangements, and has visited the officers of the Association and the leading scientific centers of the Eastern States in the interest of the meeting.

Local committees were appointed in a large number of places throughout the country to forward the interests of the Association in different regions.

A committee was appointed to inquire whether universities and other scientific institutions would set aside a week during the winter for the meetings of scientific and learned societies.

Miss Watson presented her resignation as assistant secretary of the Association, and was elected a life member in recognition of her long and efficient services.

247 new members were elected, which makes the total membership of the Association over 2,000.

The contract made by the Association with The Macmillan Company was presented. It carries out the arrangements made at the New York meeting, in accordance with which SCIENCE is sent free of charge to all members of the Association.

SCIENTIFIC NOTES AND NEWS.

WE expect to publish in early issues accounts of the scientific proceedings of the societies that met during Christmas week. In the meanwhile it may be stated that Professor W. T. Sedgwick, of the Massachusetts Institute of Technology, has been elected president of the American Society of Naturalists; Professor J. S. Kingsley, of Tufts College, president of the American Morphological Society; Professor W. H. Welch, of the Johns Hopkins University, president of the American Society of Bacteriologists; Dr. Erwin F. Smith, U. S. Department of Agriculture, president of the Society of Plant Morphology and Physiology; Dr. Frank Russell, of Harvard University, president of the Folk-lore Society; Professor Josiah Royce, of Harvard University, president of the American Psychological Association; Professor E. H. Moore, of the University of Chicago, president of the

American Mathematical Society, and Professor W. F. Clarke, of the U. S. Geological Survey, D. C., president of the American Chemical Society.

The Presidents of sections for the meeting of the British Association for the Advancement of Science, which will be held in 1901, at Glasgow, commencing on September 11th, will be as follows:

Section A.—Mathematical and Physical Science, Professor Percy A. MacMahon, F.R.S.

Section B.—Chemistry, Professor Percy Frankland, F.R.S.

Section C.—Geology, Mr. John Horne, F.R.S.

Section D.—Zoology, Professor Cossar Ewart, F.R.S.

Section E.—Geography, Dr. H. R. Mill, F.R.G.S.

Section F.—Statistics and Economic Science, Sir Robert Giffen, F.R.S.

Section G.—Engineering, Mr. R. E. Crompton.

Section H.—Anthropology, Professor D. J. Cunningham, F.R.S.

Section I.—Physiology, Professor J. G. McKendrick, F.R.S.

Section J.—Botany, Professor I. Bayley Balfour, F.R.S.

At the annual election of the New York Academy of Medicine on December 20th, the following officers were chosen: *President*, Dr. Robert F. Weir; *Vice-President*, Dr. Charles M. Dana; *Recording Secretary*, Dr. John H. Huddlestone; *Corresponding Secretary*, Dr. Louis F. Bishop.

At the meeting of the Royal Statistical Society, on December 18th, a Guy medal was awarded to Mr. J. A. Baines, for his services to statistical science and a Howard medal and a prize of one hundred dollars to Dr. J. F. J. Sykes for his essay on 'The Results of State, Municipal and organized Private Action on the Housing of the Working Class in London and other Large Cities in the United Kingdom.'

Professor W J McGee, of the Bureau of American Ethnology, has returned to Washington from a field trip through parts of Arizona, Sonora and Lower California. Outfitting at Phoenix about the middle of October, he traversed the sparsely settled plains southward to the International boundary at Santo Domingo, and thence to the village of Carborca. From this point the party worked down the sandwash of Rio San Ignacio (or Rio Altar) to the coast of the Gulf of California, where the Tepoka Indians lived until recently. Finding this tribe extinct, the expedition returned by a new route to Santo Domingo, and took the historical Yuma trail—now completely abandoned—to Rio Colorado. Here the territory of the Cocopa Indians was visited, and fairly extensive collections were for the first time made among them. Mr. DeLancey Gill, artist of the expedition, secured numerous photographs and sketches of the tribes and their territory.

Dr. L. A. Bauer, in charge of the magnetic work of the United States Coast and Geodetic Survey, returned to Washington on December 15th, after having determined the sites of the base stations for the magnetic surveys in Alaska and in the Hawaiian Islands.

Colonel Five, who was in 1896 sent by the Belgian Government on a scientific expedition to the far East, has returned home.

A memorial is being formed to commemorate the service to learning and letters of the late Professor Max Müller. The necessary steps are being taken to raise a fund, which, after providing for some personal memorial, such as a bust, relief or portrait, should be handed over to the University of Oxford, and held in trust for the promotion of learning and research in all matters relating to the history and archeology, the languages, literature, and religions of ancient India.

Dr. P. H. Kirsch died recently at Las Cruces, New Mexico. Dr. Kirsch received his doctor's degree from Indiana University about 1888. He was a teacher and naturalist of high rank, and was superintendent of schools in Franklin and other towns in Indiana and also in New Mexico. He is the author of several papers on fishes, one on the fishes of the Gila River, and another on the sturgeons.

For the purposes of the National Physical Laboratory, Queen Victoria has granted to the Royal Society, Bushey-house, Bushey-park.

The annual report of the Superintendent of Disbursements shows an increased demand on the part of the public for Government publications and recommends that the issue of the monthly catalogue be enlarged, that permission

be granted to reprint documents of public interest and that a library be established, where not only national, but also State, municipal and foreign official documents may be preserved.

A TELEGRAM has been received at the Harvard College Observatory from Professor Kreutz at Kiel Observatory, stating that a comet was discovered by Giacobini at Nice, Dec. 20^d, 313 Greenwich mean time in R. A. $22^h\ 32^m\ 0^s$ and Dec. $-22° 0' 0''$. Its daily motion in R. A. is $+6^m$ and in Dec. $-8'$. The discovery has been confirmed at the Lick Observatory, the comet having been observed by Professor Aitken on December 24th, 26th and 28th.

THE American Medical Association has appropriated $500 for researches. Applications for grants may be made during the present month to Dr. H. C. Wood, chairman of the Committee on Scientific Research, 1925 Chestnut street, Philadelphia.

THE Council of the American Chemical Society has authorized the establishment of a local section with headquarters in Kansas City.

AT a meeting of the Society of Arts, on December 12th, Professor Frank Clowes, chemical adviser to the London County Council, read a paper on 'The Treatment of London Sewage.' According to the London *Times* Professor Clowes said the present system of treatment consisted in straining or 'screening' off the larger solid matters and then mixing the sewage with solutions of lime and sulphate of iron; the chemical precipitate thus produced was then allowed to settle, together with the finer particles in the sewage, by sending the sewage slowly through parallel channels on its way to the river. The screenings or 'filth' were disposed of by being dug into the ground; the settled matter, or 'sludge' was sent in tank-steamers to be discharged out at sea; and the fairly clear 'effluent' passed constantly into the river at Beckton, Barking or Crossness. Although the condition of the river had been improved it had to be remembered that the effluent of the sewage after it had been freed from visible foul matter, still contained in invisible solution a large amount of putrescible substance, which might under suitable conditions lead to serious foulness in the stream. In 1893 the Main Drainage Committee of the London County Council started a large scale experiment on the bacterial purification of sewage. This experimental treatment had been considerably extended in its scope and the results pointed to a general conclusion that the settled sewage might be purified to a far greater degree by encouraging the spontaneous purifying action of the bacteria which were present in the sewage itself. The effluent thus produced, without the intervention of chemicals, remained free from foul putrefaction, and was able to support the life of fish. Professor Clowes proceeded to describe the bacterial treatment by means of coke beds filled three or four times per 24 hours. The maintenance of the purifying action was due to the presence of bacteria upon the coke surface and to the adequate aëration of these surfaces by frequently exposing them to the oxygen of the air. The chairman expressed the opinion that the lecturer had rightly emphasized the extreme importance of the subject as a question of sanitation. The late Professor Faraday once called attention to the foul condition of the river as evidenced by the fact that a piece of card which he threw into the water disappeared when it became immersed to the extent of only one inch. Professor Poore told them that they were altogether on the wrong track, that they ought to restore the fertilizing materials, now permitted to go to waste, to the land, without the intervention of water, but for the present, at all events, he was crying in a wilderness. The only practicable method for the present generation seemed to be to minimize the inevitable nuisance as far as possible. He wished that Professor Clowes had given them some information with regard to the cost of the processes he recommended as compared with the cheapness of letting it alone. He desired to know how much land and what sized tanks would be required for the bacteriological treatment of the whole of the London sewage. He should have been glad if the lecturer had told them whether there were not other methods of applying the activity of bacteria to the purpose in hand. It was desirable to know whether the admixture of the

salt tidal water had an injurious effect on the bacteria contained in the effluent.

UNIVERSITY AND EDUCATIONAL NEWS.

BY the will of Henry Villard, Harvard University and Columbia University each receive $50,000. Among other public bequests is one of $5,000 to the American Museum of Natural History.

RIPON COLLEGE dedicated its new science building, Ingram Hall, on December 18th. The keys of the building were presented to the trustees by the principal donor, Mr. O. H. Ingram, of Eau Claire, and received, with a fitting response by President Flagg. The principal address of the occasion was by Professor John M. Coulter, of the University of Chicago, on 'Some College Fallacies.' The building, which has been completed this fall, cost about $33,000, of which sum Mr. Ingram gave nearly $18,000 and Dr. Pearsons $5,000. The pleasant feature of the dedication exercises was a special gift by Mr. Ingram which wiped out a small debt remaining upon the building and allowed about $1,300 to be applied to the equipment. The building is three stories high and modern in all details of its construction.

THE new building of the Medical College of Cornell University was formally opened on December 29th. Addresses were made in the afternoon by President Schurman, Dr. Stimpson, professor of surgery in the College, and Governor Roosevelt. In the evening, the new building was open to invited visitors.

DR. D. K. PEARSONS has given Colorado College the $50,000 promised some time since, and it is reported that he has given Northwestern University $30,000 for the erection of a woman's dormitory and $200,000 to an educational institution, the name of which is not to be made public during his life time. A press dispatch from Chicago accounts for about two and a half million dollars given by Dr. Pearson mostly to educational institutions, and it is estimated that the sum of about five hundred thousand dollars has been given anonymously. The details of the gifts are as follows:

Beloit College	$295,000
Chicago Theological Seminary	280,000
Colorado College, Colorado Springs	150,000
Mount Holyoke College, Massachusetts	150,000
Berea College, Kentucky	150,000
Lake Forest University	125,000
Whitman College, Oregon	120,000
Knox College	100,000
Drury College, Springfield, Mo.	100,000
Yankton College, South Dakota	100,000
Presbyterian Hospital, Chicago	70,000
Pacific University, Oregon	60,000
Carleton College, Northfield, Minn.	50,000
Fargo College, North Dakota	50,000
Pomona College, California	50,000
Fairmount College, Kansas	50,000
McCormick Theological Sem., Chicago	50,000
Chicago Young Men's Christian Assoc.	40,000
Olivet College, Michigan	25,000
Marietta College, Ohio	25,000
Sheridan College, Wyoming	25,000
McKendree College	25,000
Presbyterian Board of Missions	20,000
Grand Prairie Seminary, Onarga, Ill.	20,000
Anatolia College, Turkey	20,000
Woman's Board of Foreign Missions	20,000
Chicago Art Institute	15,000
Unknown College	200,000
Northwestern University	30,000
Colorado College	50,000
Grand total	$2,465,000

It is generally believed that Dr. Pearsons' anonymous gifts will bring the total close to $3,000,000.

MR. W. J. THOMPSON, of Pittsburg, has given Washington and Jefferson College $50,000 for a library building and $10,000 for equipment.

THE Hon. Roger Wolcott, formerly governor of Massachusetts, who during his life time gave liberally to Harvard University, has by his will bequeathed $20,000 to the institution.

THE daily papers report that Mr. Alfred Vanderbilt has given $30,000 to the bi-centennial fund of Yale University.

AT the meeting of the trustees of Ripon College, December 19th, President Flagg tendered his resignation. The administrative work of the college will continue in the hands of the dean of the faculty, Professor Marsh, as it has during the fall term.

PROFESSOR ARTHUR THOMPSON, of Oxford, has been elected Professor of Anatomy in the Royal Academy, London.

A NOTABLE OFFICIAL REPORT.

IN our last issue we pointed out the urgency of an authoritative reply from the Naval Observatory to the criticisms on its management which have been uttered by parties entitled to the highest respect. We return to the subject to mention another point on which it is equally urgent that certain unfavorable impressions likely to be given by the annual report of the Observatory should be corrected. Precision and accuracy of statement are always expected in an official document, and there is no department of the government in whose reports this quality is more confidently looked for than in that of the Navy. If a report is circulated by this department containing statements likely to be misconstrued, an earnest desire that public confidence in the Navy shall not be impaired will lead us to call attention to the statements and ask that they be supported, or so changed as not to give rise to misconstruction. Especially is this the case with a paper from which astronomers the world over will draw conclusions as to the degree of precision aimed at in describing the operations of one of our scientific departments. We shall quote the passages we have in

mind and show wherein they seem to need strengthening.

"All the astronomical instruments of the Observatory have been steadily and continuously in use during the year on every clear night and day."

So comprehensive a statement as this can be made by no other observatory; and the importance assigned it is shown by the prominence of its position, and its being repeated by the Bureau in its report direct to the Secretary of the Navy. But in other passages of the report we find that the 9-in. transit circle was out of use undergoing repairs more than half the year, that little use was made of the 6-in. circle except to take the place of the 9-in., and that observations with the latter and with the photoheliograph were suspended because the observers were engaged in making preparations for the total eclipse of the sun. We find also that the total number of separate observations with the prime vertical transit was 164, less than one-half the number of nights in the year, while those with the altazimuth, used as a zenith telescope, numbered a little more than the days in the year. At the international geodetic stations the observers are expected to make about 16 double observations on every clear night. We confess to some difficulty in interpreting and reconciling these statements.

"The board chooses to assume that the salary of every professor of mathematics in the Navy, active or retired, except two at the Naval Academy, is chargeable to the expenses of the Observatory. It therefore charges in its exhibit the salaries of officers on the retired list, and the salary of one officer still on the active list whose connection with the Observatory has long since definitely ceased for cause. By such flimsy expedients as this the expense column is easily swelled."

The law provides for twelve professors on the active list. The exact number on the retired list we do not know, but certainly six, still living, have been retired from the Observatory and the Nautical Almanac Office, making a total of not less than eighteen. All but two of these would number sixteen. We find by reference to the passage alluded to in the report of the board, that five active professors with estimated salaries of $15,000 are charged to the Observatory, while the salaries of the professors retired from active duty there are estimated in the total at $10,000. The salaries of the senior ones are $3,500. We do not know whether the $8,000 estimated is or is not more than that of the three others; but it does not seem that it could be much in excess. We are therefore unable to see what ground there can be for the statement we have quoted which implies that the salaries of sixteen professors were charged to the Observatory.

In explanation of delay in publishing observations the report says:

"The delays in building, the labor of dismounting and remounting the instruments, the repairs and alterations of the same and their subsequent installation, the removal of the records and Observatory property, and generally the labor involved in settling in the new place, absorbed the entire time of the whole very limited working force of the Observatory for several years. * * * The force of the astronomical staff, sufficient for current work in settled times, was totally inadequate to bring up back work when the work had fallen behind. It was simply a physical impossibility to keep up the publications, to make the current observations and do the necessary work of removal at the same time. * * * It might have reasonably been shown that during the whole of this transition period current work was practically uninterrupted and that

the number of observations made at the old and new Observatories kept pace with those made at Greenwich. * * * The facts were laid before the board and ignored by it. They would have shown to the credit of the Observatory."

In the Observatory report for 1892 scarcely any astronomical observations are reported, except with the old equatorial, and in the report for 1893 it is still reported that few were made, 'as all the principal instruments were undergoing repairs.'

The absorption of the entire time of the working force, for several years in the manner stated; the impossibility of keeping up observations and their uninterrupted continuance, during this whole transition period on such a scale as to keep pace with Greenwich, are facts which seem to need elucidation to make them consistent. That the board of visitors ignored them is true, —the implication that it did so because they would have shown to the credit of the Observatory we leave the men concerned to answer.

"A determined effort was made by the board to prevent, if possible, the appointment of new men to fill the vacancies created by the retirement of the older professors of mathematics at the Observatory. * * * Notwithstanding the efforts of the board to prevent it, these vacancies have all been filled in line with the traditional policy of the Observatory, which has always been to take for its staff young men of promise whose career was before them, in contrast with the plan, recommended by the board, of appointing at once to high office men whose scientific reputation was already established, and whose prejudices and animosities were mature and confirmed."

We find nothing in the report of the visitors implying that 'prejudices and animosities' were to be considered as necessary qualifications for the offices to be created. It would therefore seem that, in the opinion of the head of our Observatory, astronomers whose scientific reputation is established are, as a class, 'men whose prejudices and animosities are mature and confirmed.' We can only regret that his experience should have been such as to lead to this conclusion.

A word about Leverrier and the Paris Observatory may serve to introduce a statement found in the papers appended to the 'Report of the Board of Visitors.' During the first half of the century the Paris Observatory had fallen to so low an ebb that a radical reorganization was decided upon, and Leverrier was chosen as the man to effect the desired reform.

He adopted the principle that his assistants must either quit the observatory or go to work. During his career he caused all the observations for fifty years back, which had lain unreduced, to be reduced by modern methods, arranged and published. He also kept up the regular reduction and publication of current work. Besides carrying on all this regular work, he published a vast collection of researches by himself and others, which forms one of the greatest astronomical enterprises ever undertaken by one man, and laid much of the foundation of exact astronomy up to the end of the 19th century.

In a letter to the Secretary of the Navy, found in Exhibit B, page 38, of the 'Report of the Board of Visitors,' this work is disposed of in the following terms:

"The most eminent astronomer that France has produced was an utter failure in the administration of the National Observatory at Paris, and was suc-

ceeded by an admiral of the navy under whose direction it was excellently administered.''

The fact that the officer who succeeded Leverrier was retired from active service and had devoted his energy to astronomical work with such success that, before his appointment, he had become one of the professional astronomers of the French Academy of Sciences, was not stated in the letter.

There are several other points in which the construction placed upon the Visitors' report differs essentially from that which would be placed upon it by the ordinary reader; but we shall not stop to discuss them. One is "that the Board actually proposes to remove the affairs of the Observatory from Government control." The reader of the Visitors' report will see for himself that nothing of this sort was intended.

A charge of unfairness should, however, be noticed. A comparison of personnel, salaries and total expenses at Washington shows it to cost about 50 per cent. more than Greenwich or Harvard. In the report now under review a comparison is given limited to the scientific personnel of the three observatories, and, showing that of Washington to be less in total cost, and less than half in strength, as compared with either of the others. But this only emphasizes the extraordinary number of non-scientific employees and the magnitude of the general expenses at our Observatory.

A general remark on the Visitors' report may not be out of place. The careful reader of this paper will find it marked by a moderation of tone showing a keen appreciation of the amenities of official expression, and by an avoidance of the blunt statement of unpleasant facts suggestive of the gentle influences exerted by a hospitable reception at a great government institution. A curious feature of the situation is that the plan of reform which now comes in for such scathing criticism is the outcome of an effort on the part of the Board to devise some way of making the continued administration of the Observatory as a naval station compatible with its success as a scientific institution. The Board is now, we suppose, considered as *functus officio*, but it would be interesting to know whether its individual members would, in the light of subsequent events, change their minds as to the practicability of their plan after reading such forceful criticisms from the very authority it was intended to propitiate.

Having said so much implying dissatisfaction with the report, it is a pleasure to find a serious misapprehension corrected by it. This is the common notion, shared by the Board of Visitors, that the Astronomical Director is a dual head of the Observatory. It is now made quite clear that he is only one of seven subordinate and co-equal heads of departments. We must frankly admit that this makes the proposal to have him appointed by the President, by and with the advice and consent of the Senate at a salary of $6,000, look—if not 'preposterous'—at least a little open to question.

We conclude with two questions, an answer to which we are sure would be received by all the astronomers of the country with great respect, not to say eager interest. Granting that 'no person can now pretend to be a friend of the Observatory or of science while attacking its organization,'

then if our astronomers see a great institution for promoting their science supported by Congress on a scale of unprecedented liberality, while, owing to defects of organization, the results do not come out on a corresponding scale, what is their duty as patriots and citizens in the premises?

The other and concluding question is this: What possible object can men enjoying the high and well-earned reputation which so justly accrues to the professional abilities of the officers of our Navy have in going outside the line of their profession to enter a field in which their best efforts can have no result but to lessen public confidence in their ability and good judgment? We can assure these officers that none of our citizens admire their professional skill and achievements more heartily than do the astronomers. We do not believe there is a director of an observatory in the land who would not welcome the advent of a naval officer to relieve him of the onerous duties of administration, were such a thing compatible with efficiency. But the director knows well that no such result would be possible unless the officer would consent to be subordinate to him, just as he would be the subordinate of the officer, if he performed scientific duty on a naval vessel.

THE RECENT PROGRESS OF VERTEBRATE PALEONTOLOGY IN AMERICA. *

THE three sciences especially favored by nature in this country are astronomy, paleontology and geology. American progress in astronomy is largely due to our relatively clear and dry atmosphere, as compared with that of northern Europe, to our inventive genius in the matter of instruments and to the private and public liberality which has founded great observatories and telescopes. Paleontology is also notably an American science, not because of the superior ability of its American votaries, but because of the vast extent of the arid region of the West exposing thousands of miles of fossil-bearing strata which in a moist climate would be covered by vegetation. This branch has especially enjoyed the liberality of the national government, and two men of large wealth, Professors Marsh and Cope, have devoted their entire fortunes to it. Except by institutions west of the Mississippi it cannot be pursued with limited means because of the great distances involved, the expense of fitting out explorations, and the equally great expense of preparing the fossils when they arrive in the East.

The development of paleontology in this country has followed the forest clearing of the East and the winning of the West by stage coaches and railroads. Mastodons, great sloths, horses and cetaceans were the principal animals found in the East. Among other early observers of this Eastern fauna was President Jefferson. David Owen, as U. S. Geologist between 1847 and 1852, explored the Mississippi Valley as far west as Wisconsin, Ohio and Minnesota. Joseph Leidy, the distinguished comparative anatomist of the old school, astonished the world in the fifties by describing the ancient fauna of Dakota and Nebraska. In 1870 the line extended west into Wyoming; Leidy, Marsh and Cope were all exploring and describing the types of this Eocene region with feverish haste, so that upon the average each animal was baptized with at least three names. It is our hard lot at present to find order out of this chaos of species. 'Après moi le déluge,' apparently was the motto

* Introduction and conclusion of a popular lecture illustrated by field and museum photographs., delivered at Trinity College, Hartford, Conn., on the occasion of the opening of the Hall of Natural History.

of each of these authors. As widely apart in their personal characteristics and methods of work, as it was possible to be, they were nevertheless the founders of American paleontology: Leidy, a pre-evolutionist and an exact descriptive writer, with little power of generalization; Marsh, a genius for the appreciation of the most important problems in evolution, with clearness as a writer, unrivaled talent as a collector and great powers of exact description, without marked originality in the invention of hypotheses; Cope on the other hand a philosopher, fertile in hypotheses, a road-breaker in classification, hasty in description and with indomitable capacity for work. The comparatively recent death of these three great men has totally changed the conditions of paleontology in this country, it now attracts a large number of students and has spread through our institutions. Whereas twenty-three years ago paleontology was exclusively in the hands of Marsh and Cope, we now find workers in the National Museum, the Yale Museum, at Princeton, the American Museum of Natural History, the Carnegie Museum of Pittsburg, and the Field Columbian Museum of Chicago, also in the Universities of Chicago, Kansas, Nebraska, Minnesota and Colorado. Explorations are now conducted on a most extensive scale, the peculiar American methods of work having been carried by two parties as far as Patagonia with remarkable results.

Before describing the work of the American Museum which is quite characteristic of the field at large, I want to speak of the philosophical development of this science.

The wise and oft-quoted remark of Huxley's, that the only difference between a fossil and a recent animal is that one has been dead longer than the other, is the epitome of the present attitude of our science. Huxley himself slowly reached this conclusion. After devoting the earlier years of his life to marine zoology, he shrank from accepting a post in the School of Mines, because it necessitated his centering his research upon extinct animals. Yet he became the Nestor of modern vertebrate paleontology, the first to thoroughly apply the principles of evolution as a means of interpretation of extinct forms. A fossil is still a synonym for dryness, and Huxley's preconceived prejudice, which was transformed into a passionate devotion for fossils, represents a popular error, which I trust I shall succeed in fully dissipating this afternoon; in fact, the chief burden of my song is that paleontology is a part of zoology or the study of animal life; that zoology is a part of biology; and that biology is the common-sense, the rationale, the philosophy of living nature as a whole.

The true modern spirit in which to study a fossil vertebrate is to imagine it as living, moving, walking, swimming or flying, begetting its kind. The size of the brain, which is really ascertained by studying its cavity in the skull, has been the subject of special researches by Leuret, Marsh, Cope and Bruce; the size and position of the organs of sight and smell are among the data of fossil psychology. Therefore we can study a fossil as thinking, that is, fearing its enemies, devising means of escape either by adhering to its friends in herds or by swift solitary flight. But such knowledge is not obtained from a few fragments, we need a very large part of the skeleton of an animal and information concerning its contemporaries before we can begin to draw such inferences, and one of the greatest advances of recent work consists in the fact that we have secured complete skeletons in the place of fragmentary parts.

If the remains of an animal are found with many others of its kind as in the case of five skeletons of Merycochoerus recently found by one of the American Museum expeditions, you infer that it was gregarious; if always found isolated you infer that it

led a solitary life. The construction of both teeth and feet teaches you whether it lived in the water, along the shores and swamps, in the meadows or on the dry grasses of the uplands and mountains. If an animal is found with short crowned teeth and spreading feet and its remains are always imbedded in coarse sandstones and gravels, you have an absolute demonstration that it lived and died near the river bank, if on the other hand the teeth are long crowned, adapted to the grasses, and the limbs are stilted like those of the antelope, you infer that it avoided water courses and that its remains were deposited in the fine dust like that now seen upon our western plains. This law has been recently used for a geological generalization by Dr. W. D. Matthew, which, if confirmed, will entirely overturn the lake-bottom theory long held for certain great formations of the Oligocene and Miocene east of the Rocky Mountains, as shown in this map.* It will bring in its train a whole series of consequences, because a new idea disturbs the relations of old ones just as the introduction of a new animal into a country may alter the whole balance of life. It will change our views, not only as to these eastern deposits, but as to the climate of this period; this which we have always supposed to have been extremely moist, will now prove to have been dry, not so dry as upon the western plains of the present day, but certainly as dry as in great districts in Africa. These fine dry subaërial or eolian deposits of drifting soil, containing animals of one type, are traversed by sandstone deposits due to intersecting rivers and containing animals of quite another type. This result has not been reached haphazard, but it is largely due to the exact study of extremely exact field records which are now made as to the level at which every specimen is found. The kind of rock in which a skeleton is found and even its position often forms a clue to its mode of deposition. Thus paleontology works hand in hand with geology and throws a clear light upon the climatic conditions of the past.

* Oligocene Lake.

In line with zoology is the adaptation of extinct types. The very first advice I give to my students is to ponder over the function, purpose, fitness or adaptation of parts. Comparative anatomy and paleontology are alike dry where they ignore physiology, they become fascinating in the measure that they reveal design. Consider for a moment the story told by these vertebræ, part of the backbone of a great dinosaur of 50 to 70 feet in length; they are marvels of construction, with all the beauties of the flying buttress of a cathedral and rigidity of the T truss of a modern bridge; evidently the mechanical problem which this animal solved was to combine the maximum of size and strength with the minimum of weight.

This spirit of looking for 'purpose' and ignoring the conventional distinctions between a petrified animal and a living one has been more or less characteristic of the work of the master minds of paleontology from the time of its great founder Cuvier, of Cuvier's successor, Owen, and of our own Cope. Did not Cuvier propose the law of correlation, whereby he maintained that a single claw would enable us to give the habits and restore an entire animal? A generalization, not altogether supported by more recent evidence, which in his day excited great admiration and called forth the famous remark of Balzac that 'Cuvier like Cadmus builds cities from a single tooth.' The masters of every science are always in advance of the lesser men, many of whom are seeking a bubble reputation, not at the cannon's mouth, but by the laborious description of new species. Systematic description is at once the staff of our progress and the bane of our existence. Rightly

done, it is a record of all the steps which nature has taken in the passage from lower to higher types but, alas, egotism, personal rivalry, in short every form of human frailty is here exhibited; there are the 'species makers,' who devise species which nature knows not of; the 'species lumpers' who ignore actual distinctions, putting together that which nature has put asunder, forgetting that it is a great convenience to have a name or symbol for every distinct stage of evolution; finally, there are the 'resurrectionists' who, seldom or never examining original specimens, pore over old literature and revive obsolete and best-to-be-forgotten names.

Paleontology has yet to gain universal recognition as a zoological science not only on the part of other workers, but of its own disciples. Its disciplinary value as a trainin *exact thinking in evolution* is undoubtedly superior to that afforded either by embryology or comparative anatomy.

Modern morphology or the science of form stands on a tripod of evidence. He who tries to balance a theory of vertebrate structure upon embryology or comparative anatomy alone is like a man trying to keep a permanent and comfortable sitting on a two-legged stool. It may be inconvenient to go from the laboratory so far afield as the rocks for one's evidence, but the stability of every theory which affects the hard parts of the vertebrates depends upon the tripod, namely, upon the comparison with other living types, upon the order of development from the embryo, and upon the direct history or order of evolution in past time. We are even now sympathetically witnessing the wreck of certain favorite doctrines of the greatest comparative anatomist of our day, Carl Gegenbaur, because his work rests upon comparative anatomy and embryology alone. In this regard Huxley was an unrivaled model; he not only, so far as was in his power, rested his theories upon three kinds of evidence, but let those who are hurrying through a superficial education for brief glory as investigators ponder upon the following passage, written at the age of 31: "1856–7–8 must still be 'Lehrjahre' to complete training in principles of Histology, Morphology, Physiology, Zoology, and Geology by *Monographic Work* in each Department. 1860 will then see me well grounded and ready for any special pursuits in either of these branches." This passage, in fact all of the 'Life and Letters,' constitutes at once a brilliant argument against premature specialization (Huxley little dreamt of the modern fad of extending the elective system to the kindergarten) and a solemn injunction that he who would build high must be patient to lay his foundations broad and deep.

Is there then no distinction in the methods of thinking of the paleontologist, embryologist or comparative anatomist? I would answer a distinction not of kind but of degree. Of course none of the soft parts are preserved in a fossil, the skeleton and teeth alone remain; by direct study and comparison with living types these have to be clothed with muscles, nerves and blood vessels. We are forced to study the bones and teeth with intensified keenness and exactitude in our search for evidence as to how an extinct animal moved and fed, and I consider that *precision in methods of exact description and terminology* constitutes one of the chief advances in the work of the present day.

In the geological and biological spirit this becomes a fascinating field for the constructive imagination. To do the best work you must live in the period of your research, however, remote it may be; marshal the extinct animals before you, as the brilliant young dramatist, Rostand, marshals Wagram before the eyes of L'Aiglon; revive the physical geography, the temperature, moisture, vegetation, insect life and see before

your minds eye the keen struggle for existence. * * *

* * * Here you have before you the methods and present aims of paleontology; it is the history of the world in the period which is mistakenly called prehistoric; it is your history and mine when our ancestors were struggling upwards in the long ascent of man. Every broad, serious, honest contribution to paleontology will constitute a word, a line, a chapter in the final history which our descendants will complete.

HENRY FAIRFIELD OSBORN.
COLUMBIA UNIVERSITY.

*BIOLOGY AS AN ELEMENT IN COLLEGE TRAINING.**

COURSES in natural science under the head of biology are a comparatively recent feature in our college programs. They may be described in general terms as consisting of a comparative study of certain types of animal and vegetable life with reference to their functions as well as their structures. Strictly speaking biology is in no essential respect a new subject. Nevertheless the term is a useful one, and courses in general biology differ in several important, if not essential respects, from those usually given under the title of zoology or botany or natural history. In the first place, these courses, as given in our colleges, endeavor to present the salient facts with regard to the properties of living things from a common or general standpoint. They attempt to bring into the foreground the resemblances as well as the differences in structure and function among varied forms of life belonging to both the plant and the animal kingdom. The intention is to give a bird's-eye view in which the general plan shall be made evident, and fundamental relationships shall be emphasized. A student who has acquired this point of view is prepared to appreciate discussions of the great general laws of biology, or, if need be, to enter more carefully upon a closer study of details.

But, in addition to this feature, courses in general biology are characterized by the emphasis laid upon the functional manifestations of living matter, by a presentation and discussion of the great questions of nutrition, heredity and reaction to environment.

In other words, the physiological point of view is brought out more prominently, if I mistake not, than is the case in the customary courses in botany or zoology. For these reasons a course in elementary biology has a special value, which has been recognized and has led to its very general introduction into our colleges. In a proper sequence of biological studies its place falls naturally in the college period. It should be preceded, preferably in the secondary schools, by an out-door study of the forms and life-histories of familiar plants and animals, and, on the other hand, should itself precede courses in botany or zoology or special professional training.

It is in this last respect that the importance of collegiate training in biology has been most widely recognized, that is, as a preparation for a future professional career, particularly the profession of medicine. Medicine on its scientific side falls into the group of biological studies, but as taught in the professional schools it concerns itself almost exclusively with a single, and that the most highly developed, form of life. The intelligent members of the medical profession have recognized freely that a general survey of the whole series of living types forms an excellent basis for the more special work of medical schools and medical practice, in that it gives a wholesome breadth of view and an educational training that may save its possessor from many

*Address delivered at Trinity College, Hartford, Connecticut, on the occasion of the opening of the Hall of Natural History.

a crude theory or foolish notion. It contributes, in other words, to that sound scientific foundation which is a characteristic of the well-educated physician. We find, therefore, in many or indeed in most of our colleges that courses in biology are arranged with special reference to the needs of those who expect to go into medicine. The value of this preparation is emphasized by the fact that in Great Britian all medical students are required to show evidence that they have had courses in elementary biology before entering upon their medical studies, and in this country one at least of our better schools makes a similar requirement. This intimate and recognized relationship to one of the most important professions is in itself a strong practical reason for the encouragement of undergraduate courses in biology in our colleges, for it is evident, I think, that the rapid increase in preliminary requirements now taking place in our medical schools will result in a corresponding increase in the number of those who, intending to enter medicine, will first prepare themselves by a college training. There will be in the future a greater demand from this source for biological instruction.

This relationship of biology to medicine is not, perhaps, wholly beneficial to biology, in that it tends in the minds of some to give to the subject a technical aspect which is inconsistent with pedagogical ideas of what should constitute the proper material for undergraduate study. On the contrary, it has always seemed to me that biological courses, of the kind I have in mind, are singularly well adapted to the purposes of a liberal training, that they possess both a culture and a training value entirely apart from their especial importance as a preparation for professional life. The educational value of biological work has been pointed out by many eminent writers. Huxley has summarized the arguments upon this point by showing that the work involved leads necessarily to training in observation, in comparison and classification of facts, in deduction and verification, that is in those processes of thought which enter into the intellectual life of every man. The special feature of biological training, perhaps, is the exercise it gives to the power of observation; in this respect at least it possesses a distinct advantage over other means employed to develop the mind, and I fancy that few will dispute its supremacy in this regard.

But another important influence, from the standpoint of liberal training, which may be expected from a college course in biology is frequently overlooked. I refer to the culture value of biological studies in bringing one into an intelligent relation with life on its physical as well as its psychical side. To my mind this feature is emphasized by the frequent instances one meets of crass ignorance regarding the simpler processes of bodily life. By way of example, a friend of mine, a gentleman and a scholar, a linguist of international reputation, once remarked to me that he was suffering from a headache, and he thought it probable that the fumes from his liver had gotten into his head. Evidently my friend, like some other classical scholars, had imbibed his physiological information quite incidentally from very ancient sources. With respect to modern biological knowledge his position was not more advanced than that of Brother Jasper regarding the planetary system. So, too, I am informed upon good authority that an eminent divine in this country based a certain mystical theory of his own regarding spiritual phenomena upon the fact that after amputation an individual may experience sensations in his lost fingers or toes, a fact perfectly understood by any one possessing an elementary knowledge of physiology without recourse to far-reaching mystical views.

Curiously enough, deplorable ignorance of

this kind is frequently displayed by educated men without the least sign of compunction. In fact it is usually treated in a jocund way much as when one confesses his ignorance of the latest mode in garments or of other trivial affairs of life. One may infer from this attitude that a knowledge of biology is not widespread or highly esteemed among the educated people of our time, otherwise it would not be deemed expedient to treat this knowledge with the contempt of levity. The condition that actually exists recalls the state of affairs that prevailed some two or three hundred years ago, when "Many a pretty fellow, who was a wit, too, ready of repartee, and possessed of a thousand graces would be puzzled if he had to write more than his own name." The ability to write with moderate ease is widespread now, and not even the possession of a thousand graces, would save one from a sense of humiliation if he were deficient in the elements of an English education. It would really seem desirable that our colleges should provide against the possibility of their graduates entering life a thousand years or more in arrears in all that concerns vital phenomena. So far as I am aware it is possible for a man to go through college and be instructed in the wisdom of the ancients and the history of mankind, and yet be left in a condition of child-like ignorance concerning what is known of the most striking and important phenomenon of the universe, namely, living matter and its properties.

Next to living itself there is nothing, it would seem, that should so interest mortal man as that physical basis of life through which his living is effected and in such large part influenced and controlled. Biology seeks to discover what it may concerning this substance, its structure, the laws controlling its activity, its origin, its growth, its death. These are matters concerning which every intelligent man has a natural curiosity, and concerning which every educated man ought to have some reliable information, so much at least as would enable him to appreciate the modern point of view and follow the trend of contemporaneous thought. A brief course in elementary biology meets this requirement where a course in natural history, so-called, would probably prove insufficient. The latter gives the large but external view of living nature, the former brings us into close contact with the inner structure of living matter, the medium of all the manifestations of life. On the other hand, those who have not had the advantage of some elementary instruction in biology will find that a large and important chapter in the revelations of modern science and the progress of modern civilization is written in a language which it will be difficult for them to comprehend.

When one considers the interest and importance of biology and its peculiarly intimate relations with the act of living, it becomes a fair question whether or not this side of knowledge should be represented in the course of study of every college student. It would seem to me that inasmuch as we are creatures of the senses, and must seek the foundations of our knowledge in the deliverances of the senses concerning the world without, the education of every individual should include some instruction concerning the animate as well as the inanimate world in which we find ourselves placed. He should possess some information about the means and method by which knowledge is acquired, and the external phenomena that are the occasion of this knowledge.

Moreover, the culture inculcated by natural science, both physical and biological, is a world culture that takes us back beyond the history of mankind and looks hopefully forward into the future expectant of greater and greater development. It is a culture too that we can share in common with all the sons of men, whether their classical tra-

ditions, the sources of their laws and customs and languages, are the same as ours or not. We must assume that it will become more and more important to educated men as the varied nations of the earth are brought into closer intercourse and a greater community of life.

Among the specific advantages that may be hoped from a spread of biological knowledge among the educated classes is an abatement of the surprising credulity that they often exhibit regarding natural phenomena. This credulity finds its most common manifestation in relation to diseases, their causes and their cure, and springs without doubt from ignorance of the elementary facts of biology. Men of ability and discrimination, of wide acquaintance with the affairs of life, or versed in the classical learning of the schools, are oftentimes as prone as a child or an untutored savage to be misled by the utterly irresponsible views of ignorant persons concerning the human body and its functions. From time to time in the history of medicine sects arise which propose to treat disease upon *a priori* theories that are as devoid of a rational basis as are the incantations of the Indian medicine-man. The dupes of these theories are not alone the ignorant and untrained, but frequently the well-educated. They are deceived by the shallow sophistries of quacks and charlatans, because, I fancy, the living body is to them what it was to the ancients, the seat of mysterious forces. About these mysteries they know nothing and, therefore, they are ready to believe almost anything, especially from the mouths of charlatans or self-deceived fanatics, because in the nature of things it is the latter classes that speak most positively and in the loudest tones of conviction, and such mannerisms carry much weight with most of us when we are upon unfamiliar grounds.

I am entirely willing to admit, of course, that there are more things in heaven and earth than are dreamed of in our philosophy, but this is a very vague and unsatisfactory premise upon which to erect a working hypothesis of life. I am sure that in the practical and serious affairs of life it is much better to be guided by the knowledge that we have, incomplete though it may be, rather than by wild speculations about the knowledge that we have not. The wrecks of many fantastic beliefs scattered through the history of mankind bear witness to the wisdom of this rule of conduct. It would seem that the primitive mysticism that enveloped the healer's art still clings more or less to the profession of medicine. Those who practice the art to-day, whether legitimately or illegitimately, are supposed by many who should know better, to have acquired in some way the power to lift the veil that enshrouds the mysteries of life. It would be well for the profession as well as the public if this remnant of ancient superstition could be forever effaced, and practitioners of the art of medicine could be measured by the standards of knowledge and skill that apply to less occult callings of life. For naturally this factor is used chiefly by those who are least deserving of confidence, and to the undoing of a credulous public.

We may infer that the establishment of a rational theory and practice of medicine depends nearly as much upon an education of the public as upon the training of the physician. Education in the traditional humanities does not seem to be sufficient for it is well known that those who are provided with this culture may fall easy victims to the vagaries of quacks. One might suppose that instruction in the elements of human physiology such as prevails in many colleges and secondary schools would meet the need that I am describing. But seemingly this is not the case, and the reasons for the inefficiency of this kind of

instruction are very apparent to my mind. It has none of the virtues of first-hand knowledge. Human physiology as taught in our schools is good enough in its way, but it gives no real information of the nature and properties of living matter. Outside the fact that the instruction is usually authoritative and based upon book-work, it fails to develop an acquaintance with fundamental conceptions of the nature of the living processes, and these must be comprehended in some measure if one wishes to look at the living side of nature from the proper standpoint. It may very well happen that an individual has a fair idea of his internal topography, and yet believes firmly in mad-stones as a cure for hydrophobia, or the occult influence of horse-chestnuts in the coat pocket upon rheumatic conditions, or in some similar superstition that has come down from the age of witchcraft and sorcery. These last illustrations are perhaps extreme and not generally applicable to the college graduate, but if it were desirable it would be easy to give quite specific instances of fads and theories just as unscientific and irrational which do find lodgment among the educated classes.

As an antidote to this unworthy credulity I can imagine no more certain remedy than a course in biology, including some laboratory exercises. Not a great deal is required if the instruction is real and first hand. Any one who has examined into the minute structure of living forms and gained some conception of the nature of vital processes is effectively armed against the grosser fallacies that at present find some acceptance among even the educated classes. I do not mean to say that training of this kind is indispensable for an appreciation of the nature of biological conceptions, but only that by its means the whole subject is illumined and given a reality that otherwise could scarcely be hoped for. One sees the difference fully illustrated by the attitude of the general public toward modern ideas of germ diseases and bacteria in general. How many absurdities and false notions are entertained by educated people regarding these latter forms of life!

The point that I wish to make is that in this day and generation the man or woman who goes out from college entirely uninformed on the biological side is ignorant of a very important phase of the world's history, is out of adjustment with his times, and is deprived of a most helpful means of controlling rationally his own health and that of others committed to his care. If this kind of knowledge is desirable at all as part of the armamentarium of an educated man, it is hopeless to seek for it elsewhere than in the college period. Much of the education necessary to put us into intelligent adjustment with modern life can be obtained in the secondary schools, but laboratory courses in biology can scarcely find a place so early in the scheme of instruction; they require some degree of maturity and previous training on the part of students, to say nothing of the paraphernalia requisite for actual instruction. Our college courses are crowded as it is, and perhaps it is not possible to include biology as a compulsory subject in the polymathic curriculum that is forced upon the student at present, but the opportunity at least should be freely offered. And indeed it is offered in a way in all good colleges. I only wonder that its general value is not more widely appreciated. Instead of being restricted practically to those expecting to enter the medical profession or looking forward to careers as specialists, it should be utilized by all who hope to keep abreast of the intellectual life of their times.

From a pedagogical standpoint biology is one of the most attractive subjects offered in the college programs. Outside any question of training value there are few if any subjects that lend themselves more

readily to good teaching. This peculiarity arises from the inherent human interest of the material it deals with, and by virtue of which it is easily possible to arouse the student to voluntary effort. The more I see of practical teaching the more I am convinced of the great influence that can be exerted by a teacher in this matter of stimulating the interest of students in his subject. Interest in one's work is like a brilliant light; it brings out numerous details that would be overlooked in the obscurer illumination that comes from an effort under compulsion or from a mere sense of duty, and by the same token the mental impressions produced under its influence are of a more enduring character. Real interest in one's work leads to voluntary exertion and to a concentration of attention, both of which factors produce excellent results, as regards the subject under study as well as in the matter of exercising and developing the potential capacities of the brain. I should be willing to defend this thesis purely on physiological grounds, although it is scarcely necessary, perhaps, since it seems to be fully appreciated in modern methods of teaching, particularly in the instruction of the young.

I am sure that those of us who are watching the education of our children must be struck with this fact. In former times the teacher, from the beginning, was often a task master, driving us to unwelcome labor, and when interest on the part of the pupil flagged he stirred up the circulation in the organs of thought by external applications of the rod. Learning and the rod, to use an often-quoted simile, were nail and hammer. The method was effective; temporarily, at least, it served as a means of concentrating the mind on the work in hand, but from the physiological standpoint the rod is a crude instrument, ill-adapted to mental culture. In these happier days the teacher is more frequently a friend endeavoring by gentler means to arouse in his pupils a vivid personal interest in the subjects studied, and successful in his work in proportion to his ability to effect this result. In fact, I am inclined to believe that the power to interest his students in their work is the test of a good teacher. It makes no difference how well a teacher may know his subject, nor how skilled he may be in the technical side of his calling, if he has not sufficient enthusiasm and ingenuity to put life and attractiveness into his instruction he is not doing justice to his opportunities. No student is getting the full measure of information or mental discipline out of his course unless by the interest he takes in the subject, or by some other means, he has been led to exert himself voluntarily. I feel that this consideration is quite as important in university instruction as in kindergarten teaching. I am convinced that every teacher should exert himself to devise legitimate means of arousing the interest of his student, upon the theory that they will thereby be led to think and meditate for themselves. It is for this reason, mainly, that in the natural sciences we make such extensive use of ocular demonstrations. It is not often that these demonstrations are really necessary to the comprehension of facts; their value, so it seems to me at least, lies mainly in this, that they stir the sluggish mind, they bring the brain into a condition of receptivity and activity in which it is at its best as a physiological mechanism.

That this last statement is a matter of fact and not a mere figure of speech is indicated pretty clearly by laboratory experiments. It is well known to physiologists that mental exertion is accompanied by a greater flow of blood through the brain, and that, roughly speaking, the effectiveness and intensity of the brain work is proportional to the increase in the flow of blood. We have instruments in the laboratories by

means of which we can measure these changes in blood flow, and thus approximately determine the intensity of mental activity under different conditions. I need not here describe the instrument any further than to say that it consists of an apparatus for measuring the volume of the hand or arm. When the brain is working actively the arm shrinks in size, the shrinkage being due to a shunting, so to speak, of some of its blood to the brain. I have had occasion to use this apparatus repeatedly in my laboratory, and the results seem to indicate quite clearly that an important factor in bringing about increased circulation through the brain, and therefore probably an accompanying intensity of brain activity, is that of a high degree of interest in the subject of thought or discussion.

I may be permitted to describe one or two incidents which, though trivial in themselves, illustrate the point I am making. It happened on one occasion that a graduate student in my laboratory, a Catholic priest, was using this apparatus in the course of some investigations upon the physiological effects of pleasant and unpleasant sensations. In connection with his problem he made a number of tests of the effect of strong mental activity upon the circulation. In one of these experiments he had a young theological student in the apparatus and was putting him through an examination, with the result that the record showed some indication of increased mental activity. He had arranged, however, that while the experiment was in progress one of the young man's regular teachers should appear suddenly upon the scene and pretend to give him his final examination which was due at about that time. The ruse succeeded admirably; the student took the examination seriously and the effect upon his arm was so great that the apparatus was unable to record the full extent of its shrinkage. It was a capital illustration of the effect on the circulatory system of intense mental activity when accompanied by some degree of emotional excitement; or as a Methodist Bishop, to whom I was showing the record, expressed himself, it showed the serious effect that dogmatic theology may have on the extremities.

On another occasion, a colleague of the priest, who was himself an instructor in a theological seminary, was placed in the apparatus and subjected to an examination. The result upon his extremities was very slight. The truth was that he was on familiar grounds, he was as well acquainted with the subject as his interlocutor, and perhaps was a little weary of it. The experimenter, however, recalled that his friend was from Kentucky and began to ask some questions concerning the blue-grass region, the breeds of race-horses and horses in general. He was delighted to find that he not only got an enthusiastic and minute description of the region and its famous racers, but, that his apparatus gave most satisfactory indications that the sluggish brain had been fully aroused, and was working in its best form as regards the subject under discussion.

Many similar results obtained by other observers bear witness to the general truth that the element of interest is an important factor in stimulating brain activity, and so acting upon the vaso-motor centers as to put this organ under its most favorable physiological conditions for work. The brain that is but half aroused and interested is in fact partly unconscious. Much that it sees or hears fails utterly to awaken that chain of associations, that synthesis and comparison of memory records which forms the physical basis of mental growth and training.

It is possible, I believe, that this factor is not entirely appreciated in our college teaching. Some weight, indeed consider-

able weight should be given to it, not only in the individual work of the teacher, but in the construction of courses. I do not mean, of course, that in making the curriculum this consideration should have a predominating influence, but it should certainly be borne in mind. Other things being equal the subject that has the most intrinsic interest is likely to have the highest degree of training and developing value, and I feel safe in asserting that this virtue is possessed to an uncommon degree by the subject of biology. Its importance in illustrating the methods of scientific thought, and the practical utility in life of its subject matter are combined with an attractiveness that appeals to every intelligent person.

To have under the eye the primitive forms of life in all their strange and suggestive variations, to follow the development of an apparently simple and structureless ovum into a complicated and exquisitely constructed organism and to see these various stages in the individual history paralleled in nature by the slow phylogenetic growth of animal forms, to realize for one's self the community of structure and function that binds together all living beings, these things are of a nature to awaken interest in the minds of the most careless. Such at least was my personal experience as a student, and such has been my observation upon many classes composed of men with varied training and widely different purposes in life. Just as an elementary study of astronomy lifts one out of his self-sufficient narrowness and brings him face to face with great thoughts and problems, so an acquaintance with the teeming existence of the microscopic world leads us to a thoughtful, intelligent and humble consideration of the great mysteries of the universe.

The desirability of having some form of biological work represented in our college courses commends itself to my mind for still another reason which has, I believe, some practical basis. I refer to the fact that during a man's college life it is necessary as a rule that some decision shall be reached concerning the character of his future career. There are some, doubtless, among our college students upon whose conscience the necessity of making this decision rests but lightly, by reason of the exuberant hopefulness and confidence of youth, yet upon the whole I fancy that few students in their senior year fail to give this serious subject much careful and anxious consideration. Motives of expediency or the advice of parents or friends frequently furnish the controlling factor in the decision to which he finally comes, but individually he must desire and seek for some light, from his own experience, regarding his personal fitness and adaptability for the various possible careers that lie before him. It is a sad business when the search is fruitless, and he stands at the parting of the ways, undecided, not knowing which path offers to him the greatest chances of happiness, usefulness and success. It seems to me that a student's college course should be of direct assistance to him in this matter of his life's work, not only in giving him a general training that shall send him forth equipped for competition with his fellows, and prepared to enjoy the usufruct of the world's intellectual inheritance, but specifically in throwing light upon the nature of his own talents. In some way this period of preparation and training should be adapted to enable the individual to find himself, to discover wherein lie his greatest interests and greatest possibility of success and happiness. For this reason it would seem to be a mistake if a department of knowledge so important and peculiar as biology is not brought in some way to the student's attention. It forms the gateway to at least one great profession which though overcrowded at present is in

reality suffering from the lack of men with college training.

If our colleges could turn into the profession of medicine those of their students who find within themselves a peculiar adaptability to its work, to take the place of the thousands of uneducated men who at present are attracted to it by commercial motives alone, they would accomplish a most useful work for humanity at large.

W. H. HOWELL.

JOHNS HOPKINS UNIVERSITY.

THE OPENING OF THE HALL OF NATURAL HISTORY, TRINITY COLLEGE.

ON December 7th the new Hall of Natural History of Trinity College was formally opened.

The Rev. George Williamson Smith, D.D., President of the College, delivered the address of welcome, as follows:

"It gives me great pleasure to welcome you to Trinity College on this occasion. It is the realization of what was undertaken by the trustees of Washington College when they issued their prospectus in 1824. In that prospectus we find that professors had been appointed for departments of chemistry and mineralogy, of agriculture and political economy, and of botany. A professor of natural philosophy was to be appointed at an early day. It was a radical departure from the college curriculum accepted at that time to give such a large place to scientific study, and the difference was increased by a provision that students could be admitted to 'pursue such *particular studies* as might be suited to their circumstances,' 'or as the inclination of their parents or guardians might require.' The additional announcement that 'if, in the end' of their association with the college, 'the amount of the attainments' of special students 'should be judged by the faculty to be equal to the knowledge acquired in the regular course, they might be candidates for the Degrees in Arts, which would be conferred on the students in that course,' is still regarded as revolutionary in most of our colleges.

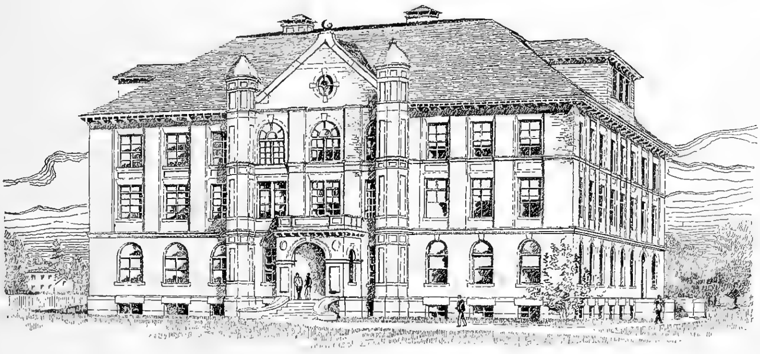

FIG. 1. The Hall of Natural History.

"The position and importance given to scientific studies attracted a large number of students who wished to prepare for the study of medicine or for scientific pursuits, and among the early students a large proportion became distinguished physicians.

Among the special students in 1829 was James H. Ward, a midshipman of the United States Navy, who was preparing for the examination for past-midshipman, and who found in Washington College the opportunities for such studies as he desired to pursue and which were cultivated in only a few places. It was largely through his instrumentality that the United States Naval Academy was founded by Bancroft in 1844.

"But the men who founded Washington College, with its startling departure from the accepted course of study, were half a century in advance of their day; and it is as fatal to a man's usefulness to be fifty years ahead of his time as to be fifty years behind it. The college was compelled to recede from its advanced position and do the work called for in its generation. But the scientific studies, though reduced, were never abandoned. A few years ago, by the generosity of alumni and friends of the college, among whom the late Junius S. Morgan, of London, and Mr. Walter Keney, of Hartford, were conspicuous, but particularly by the large gift of the late George A. Jarvis, of Brooklyn, N. Y., the laboratories for physics and chemistry were constructed and equipped. In 1888 tentative efforts were made to procure the funds for the erection of a building for the museum and department of natural history. The time was not deemed favorable and the project slept until 1893, when another effort was made. But the flurry of a threatened war with England over the Venezuelan boundary caused another postponement. In 1898 the effort was renewed; several large subscriptions were obtained, W. C. Brocklesby, an alumnus of the college, whose father had been for many years a professor in charge of the work of natural history, was engaged as architect, and to-day we have the satisfaction of seeing the completion of this part of the project of our venerated founder and his associates. In their name, as well as our own, I bid you welcome."

In addition to the addresses by Professor H. F. Osborn and Professor W. H. Howell given above, short addresses were made by Professor Hadley, of Yale; President Carter, of Williams; Professor Conn, of Wesleyan and ex-President Pynchen, of Trinity.

The following extracts from congratulatory letters to Professor Edwards were read:

"The generous support which is afforded by your countrymen to scientific institutions is in the highest degree creditable to the nation and sadly contrasts with the treatment accorded to naturalists in the old country.

"I need hardly say that I am fully aware of the splendid contributions to the various branches of natural history which have been made by members of the staff of the various universities and colleges of the United States, and I trust that the magnificent scientific reputation of such men as Louis and Alexander Agassiz, Asa Gray, T. D. Dana, and O. C. Marsh may serve as an incitement to their successors in similar lines of research, and that the mantle which they dropped may abide with future generations in Trinity College, Hartford. Believe me, dear sir,

"Very faithfully yours,

"ROBERT D. CUNNINGHAM, M.D."

PROFESSOR OF NATURAL HISTORY,
QUEEN'S COLLEGE, BELFAST, IRELAND.

"It is my wish that your new hall may receive and instruct many generations of students, and that it may inspire in many the taste for zoology.

"Very cordially yours,

"L. CUÉNOT."

PROFESSOR OF ZOOLOGY AND PHYSIOLOGY,
UNIVERSITY OF NANCY, FRANCE.

"With all good wishes for the success of your labor, I am

"Yours very faithfully,

"FRANCIS DARWIN."

CAMBRIDGE, ENGLAND,
August 15, 1900.

"I regret that distance, and the occupations that fill the life of all those who have devoted themselves to science, do not permit me to be present in person at the inauguration of the Laboratory of Natural History of your college. But I am with you in heart, and I send you in this letter my most earnest wishes for the success of your laboratory.

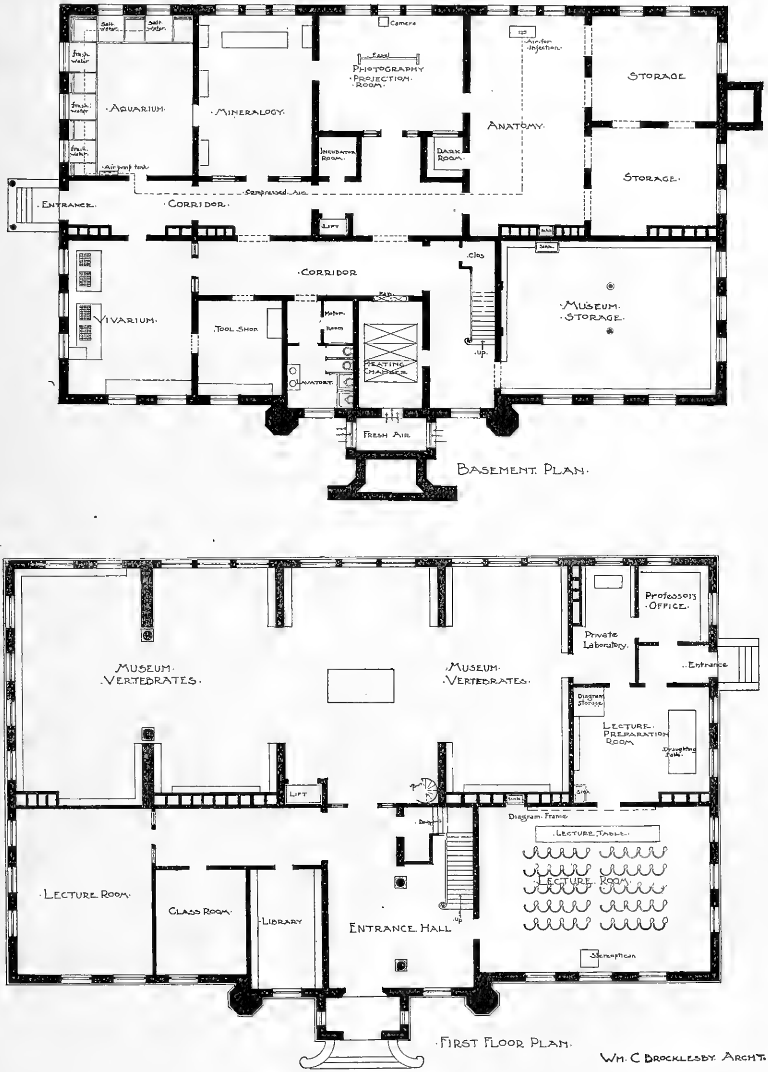

FIG. 2. Hall of Natural History.

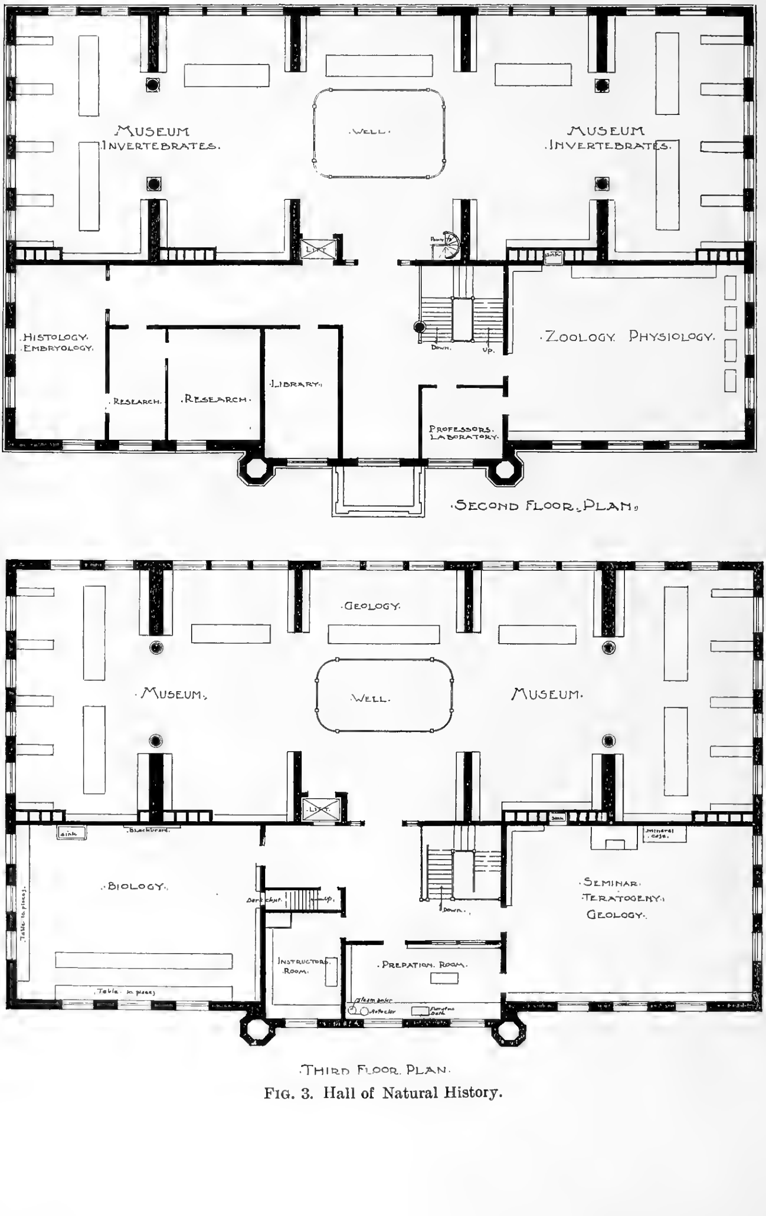

Fig. 3. Hall of Natural History.

"Moreover, there can be no doubt of this success, for you will display there, you, your associates in labor and your pupils, the remarkable qualities of your race, and you will be with us in the vanguard in the great battle that we are fighting without truce for the discovery of the truth, a noble conflict in which all the combatants participate in the advantages of victory, and which causes to flow neither blood nor tears.

"YVES DELAGE."

PROFESSOR OF ZOOLOGY AND COMPARATIVE ANATOMY, UNIVERSITY OF PARIS, FRANCE.

"I wish your new Hall of Natural History the very best success. I am

"Yours very respectfully,

"PROFESSOR DR. ANTON DOHRN."

ZOOLOGICAL STATION, NAPLES, ITALY.

"I send you my best wishes for the opening of your new Natural History Institute in Trinity College, and hope it will bring to maturity many advances in the investigation of the grand treasures of Nature of your beautiful country, which I had the pleasure of becoming acquainted with last year. With greatest esteem,

"Yours truly,

PROFESSOR D. A. FOREL."

ZURICH, SWITZERLAND.

"Thank you very much for the sending of your program of instruction, which I have read with the greatest interest. I congratulate you upon the problem which you have set for yourself; that zoology and anatomy can only gain when they are permeated by physiological and general biological principles, is, alas, not yet recognized to any extent. Only in botany is recognized the natural union of form and function in teaching, and there but to a slight degree; this has found expression in the splendid book of Haberlandt, 'Physiological Anatomy.' Mineralogy and geology in Zurich have undergone a similar process.

"To the anatomist and zoologist on the contrary, the comparative method is allowed, and the so-called 'purely mechanical' points of view are repudiated.

"Yours truly,

"MAX VON FREY."

UNIVERSITY OF WÜRZBURG, GERMANY.

"May the Hall of Natural History be a complete success—fulfilling all the aspirations of its founders and well-wishers! Had it been possible it would have afforded me much pleasure and satisfaction to have been present at your opening function. All I can do now is to wish the institution and yourself Godspeed!

"Yours very truly,

"JAMES GEIKIE."

UNIVERSITY OF EDINBURGH, SCOTLAND.

"I should have been happy to express personally to you my great admiration for the powerful scientific movement taking place in the United States of America, the proof of which is given by the erection of so many splendid universities. I send you my heartiest wishes that the Biological Laboratory of Hartford may soon produce numerous and excellent works in all branches of modern biology. Believe me, dear sir,

"Yours very sincerely,

"A. GIARD."

MEMBRE DE L'INSTITUT DE FRANCE.

"In reply to your invitation I wish to send, in my absence, a few words of hearty greeting on the occasion of the opening of your Hall of Natural History. I hold it an imperative duty of the minister of every denomination of religion to seek to understand the modes of thought of his flock. And considering the way biological progress has influenced man's way of looking at things generally, it seems to me that its study is one specially necessary for the ministry. The work of the churches or great social bond of union and progress in humanity is one we all recognize. That men anxious and willing to work for this end should have had their services unutilized in the past—the very recent past—through the lack of understanding of the theologians is a fact to be deeply regretted. And the new foundation in your college should make for charity in human fellowship, through and with the advancement of human knowledge. I am, gentlemen,

"Faithfully yours,

"MARCUS HARTZOG, D.SC., M.D., F.L.S."

PROFESSOR OF NATURAL HISTORY, QUEEN'S COLLEGE, CORK, IRELAND.

"The natural sciences, and not in the least biology, have in a few decades developed remarkably in the United States. Proof of this are the newly founded, splendidly equipped universities, natural history museums, marine biological stations, and recently published journals, by means of which science has already experienced so many additions due to American research.

"That the newly erected 'Hall of Natural History of Trinity College,' placed under your guidance, may

develop to a worthy home of the natural sciences, I wish from all my heart.

"Yours truly,

"Dr. Oscar Hertwig."

University of Berlin,
Germany.

"I express my interest in the erection of your institute. Its creation will be a new proof of the successful zeal with which the younger school of your country is occupied to further scientific progress in unconfined research, as well as in the dissemination of knowledge. With the most respectful greetings,

"Yours truly,

"William His."

University of Leipzig,
Germany.

"You may perhaps be surprised to hear that I passed two very happy years of my boyhood in Hartford, attending the high school, and that I still count among my best friends a number of Hartford people. You may, therefore, imagine with what satisfaction I learned that in the city with which my personal relations, so to speak, are very intimate, a hall has been established in which the subjects in my own special lines are to be studied. I congratulate the city, the College and you on the completion of the Hall of Natural History, and hope that it will become a center of scientific activities and will do its full share in the advancement of knowledge, as it no doubt will. With best wishes, I remain

"Yours sincerely,

"K. Mitsukuri."

Imperial University,
Tokio, Japan,

"I have much pleasure in sending you my best wishes for the new Hall of Natural History at Trinity College, Hartford. May it have a long, useful and prosperous career. May it train many men to do good and honest work in natural history, that most delightful of the sciences, and may financial blight—that curse of so many scientific undertakings, never fall upon it! I much regret that I cannot myself be present on the occasion to offer my congratulations in person.

"It is now exactly a quarter of a century since I began the study of Natural History under that brilliant zoologist, that truly great and distinguished man, Francis Maitland Balfour. The lessons I learnt from him I would fain teach to others, and it has always been my endeavor to do so. The most important of them were—thoroughness and honesty in work, the realization of the fact that no scientific work is worth doing unless it be done primarily for the sake of the work, and not primarily for the sake of the worker. The realization of this fact is the most important result which a sound education can produce.

"I cannot wish you anything better than this—that the work done in your institution may be honest work, sound work, work which men of all countries and all languages who are seeking after truth may turn to with confidence, that there at least they will find the real thing—an honest record of painstaking observation.

"In other words, may your institution be the means of training men to work like Johannes Müller, Charles Darwin, Thomas Henry Huxley, Albert Kölliker, Elias Metschnikoff and Francis Maitland Balfour. I am, dear sir,

"Yours sincerely,

"Adam Sedgwick."

Reader in Morphology and Embryology of Animals, Trinity College, University of Cambridge, England.

"I pledge you my sincerest wishes for the new Hall of Natural History of Trinity College. May it take its place in contributing to the greatest researches which the United States have produced in the last decennium for our sciences, and which have stirred up the admiration, yes, I may say, the envy of the entire Old World. With this wish, I remain, in greatest esteem,

"Yours truly,

"Dr. J. W. Spengel."

University of Giessen,
Germany.

"I express my admiration and forcible acknowledgment of how zealous your countrymen in the great country of the United States are to further science in every direction ; I wish Trinity College and especially its scientific institutes the greatest success and development.

"Most respectfully yours,

"Waldeyer."

University of Berlin,
Germany.

"Kindly accept my wishes for the success of this solemnity and for the ever progressive development of the knowledge of truth, as well as of the spirit of research in your university.

"I beg you, sir and your colleagues, to accept the expression of my cordial appreciation.

"Emile Yung."

Professor of Zoology and of Comparative Anatomy in the University of Geneva, Switzerland.

In addition letters were received from:

Professor Henry Blanc, University of Lausanne, France.

Professor Wilhelm Blasius, University of Braunschweig, Germany.

Professor O. Bütschli, University of Heidelberg, Germany.

Professor Carl Chun, University of Leipzig, Germany.

Professor E. Ehlers, University of Göttingen, Germany.

Sir Michael Foster, University of Cambridge, England.

Professor A. A. W. Hubrecht, of Utrecht, Holland.

Professor Alexander Kovalevskij, St. Petersburg, Russia.

Professor W. N. Parker, University College, Cardiff Wales.

Professor E. B. Poulton, University of Oxford, England.

Professor Dr. Louis Roule, University of Toulouse, France.

Professor G. O. Sars, Christiania, Norway.

Professor Dr. Franz Eilhard Schulze, University of Berlin, Germany.

Professor Aleksandr Andrejevid Tichomirov, University of Moscow, Russia.

Professor Sydney Howard Vines, University of Oxford, England.

Professor S. Watasé, University of Tokio, Japan.

Professor R. Wiedersheim, University of Freiburg, Germany.

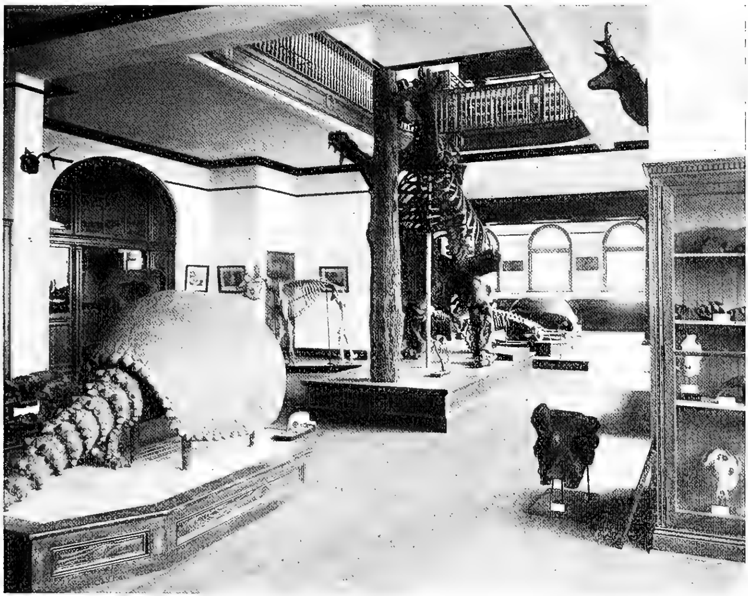

FIG. 4. Museum.

Professor Hubert Ludwig, University of Bonn, Germany.

Professor H. N. Mackintosh, Trinity College, Dublin, Ireland.

Professor K. Möbius, University of Berlin, Germany.

THE HALL OF NATURAL HISTORY.

The building having a frontage to the north of 122 feet, and a width of 72 feet, is three stories high above an ample basement. The materials used are common

brick, molded brick and sandstone for finish.

In plan the building is a parallelogram, with a central projection 40 feet wide, flanked by octagonal turrets extending through the several stories and finished above the main roof line. The principal entrance gives access to a wide staircase hall. Directly opposite this entrance is the doorway to the Museum.

The Museum occupies three floors, the two upper ones having each an area of over 4,650 square feet, the first floor being connected with the second by an iron staircase and a large floor-well, which forms a feature in the construction of the second floor. The whole Museum has a southern exposure and is adequately lighted.

The arrangement of rooms is shown in the accompanying diagrams.

A feature of the equipment is the aquarium and vivarium rooms in the basement. In the aquarium there are five tanks, each containing 290 gallons, paneled off from the main room as in the Berlin, Washington, Battery Park and other aquaria. Thus the public can see the animals under the most favorable conditions, while in the aquarium section the students may work at problems in comparative physiology and comparative psychology without being disturbed. Three of the tanks are for marine and two for fresh-water animals and plants. The great advantage, as an adjunct to teaching, of having alive such animals as medusæ, star-fish, sea-cucumbers and anemones is apparent to

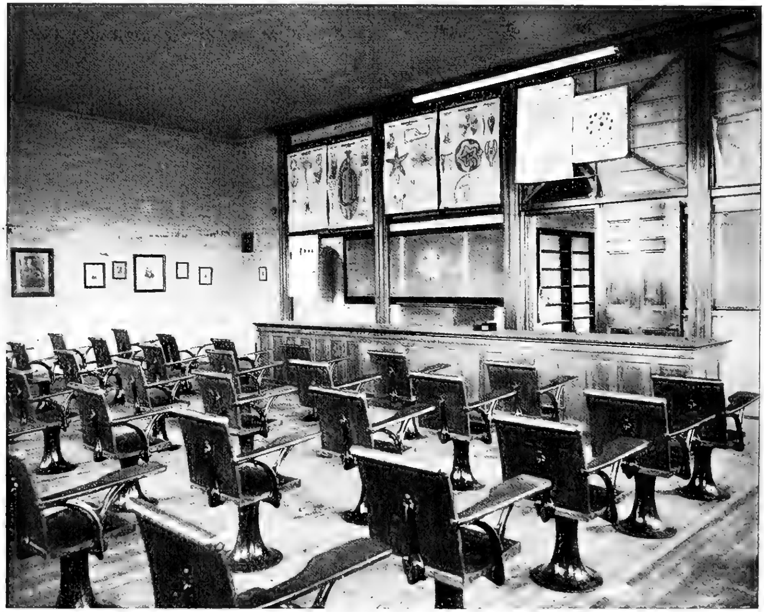

FIG. 5. Lecture Room.

anyone who has attempted to gain a natural conception of such forms from only alcoholic material. In the attic is a large pigeon house for breeding purposes. Glass beehives and ant nests are used for the study of community life. In fact, it is planned to have every order of animals represented by typical species in the aquaria and vivaria, so that the study of function may go hand in hand with the study of form.

In the museum each order is represented by specimens in alcohol, skins, skeletons, a dissection accompanied by a water-color sketch, with all the parts plainly labeled and embryological models with explanatory charts, in order that the visitor or student may learn as much as possible of the forms exhibited rather than become overwhelmed with the wealth of species.

AN ARTIFICIAL REPRESENTATION OF A TOTAL SOLAR ECLIPSE.

IN preparing for polarization experiments on the solar corona it is extremely desirable to have an artificial corona as nearly as possible resembling the reality, for preliminary work. The only device of the kind that has been used to my knowledge is the arrangement described by Wright in his eclipse report, consisting of a cardboard funnel, lined with black cloth, with a light at the back. This gives a ring-shaped illuminated area radially polarized. It is believed that the contrivance about to be described will be found far better adapted to work of this sort, for the artificial corona in this case resembles the real so closely as to startle one who has actually witnessed a total solar eclipse; the polarization is radial, and is produced in the same way as in the sun's surroundings, and the misty gradations of brilliancy are present as well. So perfect was the representation that I added several features of purely æsthetic nature, to heighten the effect, and finally succeeded in getting a reproduction of a solar eclipse which could hardly be distinguished from the reality, except that the polar streamers are straight as drawn by Trouvelot, instead of being curved, as all the recent photographs show them. The curious greenish-blue color of the sky and the peculiar pearly luster and misty appearance are faithfully reproduced. For lecture purposes an artificial eclipse of this sort would be admirably adapted, and I know of no way in which an audience could be given so vivid an idea of the beauty of the phenomenon. Drawings and photographs are wholly inadequate in giving any notion of the actual appearance of the sun's surroundings, and I feel sure that any one will feel amply repaid for the small amount of trouble necessary in fitting up the arrangement which I shall describe.

A rectangular glass tank about a foot square on the front and five or six inches wide, and a six-candle-power incandescent lamp are all that are necessary. The dimensions of the tank are not of much importance, a small aquarium being admirably adapted for the purpose. The tank should be nearly filled with clean water, and a spoonful or two (the right amount determined by experiment) of a weak alcoholic solution of mastic should be added. The mastic is at once thrown down as an exceedingly fine precipitate, giving the water a milky appearance. The wires leading to the lamp should be passed through a short glass tube, and the lamp fastened to the end of the tube with sealing wax, taking care to make a tight joint, to prevent the water from entering the tube. (Fig. 1.) Five or six strips of tin foil are now fastened with shellac along the sides of the lamp,

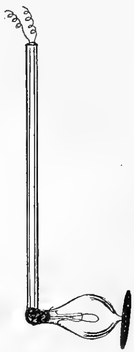

FIG. 1.

leaving a space of from $\frac{1}{2}$ to 1 mm. between them. The strips should be of about the same width as the clear spaces. They are to be mounted in two groups on opposite sides of the lamp, and the rays passing between them produce the polar streamers. The proper number, width and distribution of the strips necessary to produce the most realistic effect can be easily determined by experiment.* A circular disk of metal, a trifle larger than the lamp, should be fastened to the tip of the lamp with sealing-wax, or any soft, water-resisting cement; this cuts off the direct light of the lamp and represents the dark disk of the moon. The whole is to be immersed in the tank, with the lamp in a horizontal position, and the metal disk close against the front glass plate. (Fig. 2.) It is a good plan to have a rheostat in circuit with the lamp to regulate the intensity of the illumination. On turning on the current and seating ourselves in front of the tank we shall see a most beautiful corona, caused by the scattering of the light of the lamp by the small particles of mastic suspended in the water. If we look at it through a Nicol prism we shall find that it is radially polarized, a dark area appearing on each side of the lamp, which turns as we turn the Nicol. The illumination is not uniform around the lamp, owing to unsymmetrical distribution of the candle power, and this heightens the effect. If the polar streamers are found to be too sharply defined or too wide, the defect can be easily remedied by altering the tin-foil strips. The eclipse is not yet perfect, however, the illumination of the sky background being too white and too brilliant in comparison. By adding a solution of some bluish-green aniline dye (I used malachite green) the sky can be given its weird color, and the corona brought out much more distinctly. If the proper amount

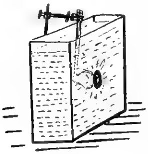

FIG. 2.

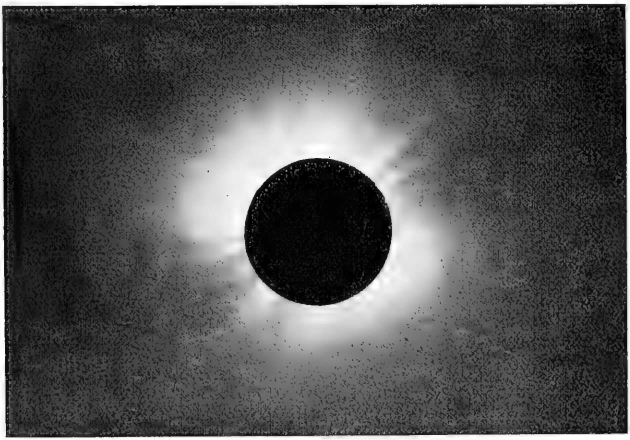

FIG. 3.

* Probably black paint could be used instead of the tin-foil strips.

of the dye be added, the sky can be strongly colored without apparently changing the color of the corona in the slightest degree, a rather surprising circumstance, since both are produced by the same means. We should have now a most beautiful and perfect reproduction of the wonderful atmosphere around the sun, a corona of pure golden white light, with pearly luster and exquisite texture, the misty streamers stretching out until lost on the bluish-green background of the sky. The rifts or darker areas due to the unequal illumination are present as well as the polar streamers. The effect is heightened if the eyes are partially closed.

A photograph of one of these artificial eclipses is reproduced in Fig. 3. Much of the fine detail present in the negative is lost in the print, and still more will doubtless go in the process of reproduction. The coronal streamers extend out much farther than is indicated by the photograph. No especial pains were taken to get the polar rays just right.

UNIVERSITY OF WISCONSIN.

SCIENTIFIC BOOKS.

Street Pavements and Paving Materials. A Manual of City Pavements: the Methods and Materials of their Construction. For the use of Students, Engineers and City Officials. By GEORGE W. TILLSON, C.E., President Brooklyn Engineers' Club, etc. New York, John Wiley & Sons. 1900.

As might be inferred from the title, this is a very pretentious book. The design of the author appears to have been to exhaust the subject. A very careful examination of the book has convinced the reviewer that for the purpose of the reviewer the accomplishment of this design may be divided into two parts: (1) That portion of the book that comes strictly within the perview of the engineer, and (2) that portion which does not.

Before proceeding to the consideration of these parts we wish to remark certain conditions that relate to the work as a whole. The author does not appear to have been impressed with the gravity and seriousness of the great work he has undertaken, but a certain atmosphere of flippancy pervades some of the most important discussions; as witness his definition of the word Bitumen on page 43.

Again, either the manuscript was very carelessly prepared, or the proofs were very carelessly read, for the grave errors that are too numerous to mention can hardly be laid to the account of the printer. For illustration turn to page 53. The sentence, "He contends that by the use of petroleum ether a large amount of asphaltene is dissolved and is consequently called asphaltene," is nonsense, as it stands; the last word should be 'petrolene.' Further on he says, "I had to admit, and do admit, that the analysis as carried out by the later methods suffices to make identity or nonentity of two samples probable or highy probable." Nonentity should be nonidentity, and highy should be highly. To point out all the errors of this description would require too much space.

That portion of the work that relates strictly to engineering problems appears to be carefully prepared, and the various problems discussed appear to be treated with intelligence and discrimination. Had Mr. Tillson, as an engineer, discussed seriously and carefully read the proofs of a work devoted to the engineering problems involved in street paving, we do not doubt that a very valuable book would have been the result. For Mr. Tillson has reaped a field of immense extent, and he has brought together an immense amount of detail from widely separated sources and has brought them into convenient form. For this his fellow members of the engineering profession, and a wider clientage of miscellaneous readers outside his profession would have doubtless given him appreciative thanks. But, as before stated, Mr. Tillson has attempted, in a very pretentious way, to exhaust his subject, and has wandered far beyond the borders of his profession of engineering, thereby committing the blunder of attempting to treat subjects learnedly of which he has no knowledge. For engineers as a class are not trained in general science. They are

trained as engineers and have a fairly generous knowledge of physics, with only a smattering of chemistry, mineralogy and geology; yet following the example of the French engineers, which I have elsewhere mentioned, they seem to have a propensity for the discussion of the origin and properties of bitumens, a discussion which involves some of the most intricate problems in the sciences above mentioned now engaging the attention of scientific men. Hence, it is not strange, that outside the engineering problems which it treats intelligently, this book should be a chaotic jumble, brought together without chronological arrangement, without order as to the natural divisions of subjects, and discussed without discrimination and without satisfactory result. These defects of judgment and purpose would have been greatly mitigated if Mr. Tillson had not committed two unpardonable offences as an author. First, he cites from authors all over the world without giving in a single instance reference to the original memoirs, by which a reader can verify or extend the passage cited. Second, he has attributed to authors cited, language that they have never used, by substituting for the author's language his own abstract or paraphrase. In illustration, see page 43, where he patches up a definition of 'bitumen' by 'transposing Professor Sadtler's words and adding some of Mr. Richardson's.' He puts this patchwork that neither Sadtler nor Richardson would recognize, in quotation marks. From whom is it quoted? Again, on page 53, he quotes from my 'Tenth Census Report.' I read the passage with amazement. I knew I had never used such language. When I turned to the report I found that Mr. Tillson had substituted his own paraphrase for the language used by myself and had enclosed it in quotation marks. Comment on such atrocious work is unnecessary.

It would require too much time and space to show in detail all the blunders that are found in the nearly 40 pages devoted to 'Asphalt.' One other must suffice. This book is infested with the ill-disguised fallacy that material from the Trinidad Pitch Lake is superior to all other for street pavements. The old threadbare story of Eighth Avenue is rehearsed, etc.

I regret the necessity of such unqualified condemnation of much of this book; but the character of the criticism results from the nature of the case. I think I am safe in assuming that no railroad corporation would employ a chemist to construct a skew-arched bridge.

S. F. PECKHAM.

American Education and What Shall It Be? Preliminary Report of the Committee of the Society for the Promotion of Engineering Education; made at the New York Meeting, July 2, 3, 1900. Reprinted, with discussion, from the Annual Volume of Proceedings; H. S. JACOBY, Secretary, Ithaca, N. Y. 8vo. Pp. 74. Price, 25 cents.

One of the speakers in the discussion began with the remark that this report marks an era in its department, that it was the first document of the sort which, so far as he had observed, recognized the fact that there may be 'many educations.' While it may not be the fact that the publication of this report was the first recognition of the necessity of various educations for various sorts and conditions of men,* it is probably the first in which the fact of a variety of educations as a need of the time being recognized by authority is itself noted. The document is a reprint, from the transactions of the Society, of the report of a committee consisting of six representative educators in applied science and technical subjects, selected from representative institutions at Madison, St. Louis, Ithaca, Minneapolis, Boston and Philadelphia, who were requested to endeavor to give formal expression to the views held by them collectively on the question above quoted in the title of the paper thus prepared.

Space does not here permit of the presentation of any full abstract of the report, which is one which should be carefully read by every educator—and by our legislators even more carefully, if possible. The discussion is no less suggestive and invaluable than the report; a considerable number of well-known teachers and engineers taking part.

* 'The Mechanic Arts and Modern Educations,' an address delivered at Richmond, Va., before the Mechanics' Institute of Virginia, by R. H. Thurston, May 18, 1894, Richmond, Va. William Ellis Jones. 1894 12mo. Pp. 23.

The committee agrees that there is a place for many kinds of school, and that they, as a rule, have their separate purposes and are, in fact, not competitors either among themselves or with the common school system of the country. Manual training schools, in which, as Dr. Woodward has said, 'the whole boy is sent to school,' are commended as adjuncts to the existing system, and, as a matter of fact, such schools are rapidly becoming incorporated into the common school systems of our larger cities and industrial towns. Manual training and art education are considered desirable as a part of all public school education, and provision should be made in them for both boys and girls, each in a suitable manner. The committee considers such a combination to be 'the ideal public school' for our country. The State agricultural and mechanical colleges constitute, in many of our States, another and important class, and are doing work which is adjudged to be far more than a compensation for their cost to the people. They are usually true secondary industrial schools, but they apparently divert many young men from agriculture into mechanical vocations. Minnesota, however, for example, and some other States, have very successful schools of agriculture.*

The higher engineering schools are considered to be strictly professional schools of a high grade, which 'rank with the best' in any country. Our monotechnic or trade schools are still to be founded. They are considered to constitute the greatest need of the educational system. While the committee asserts that 'all schooling should lead primarily to the elevation and development of the individual, and only secondarily to a greater material prosperity,' and italicizes the statement, it is considered, nevertheless, imperative that such institutions be established, if we are to hold our own, in the future, in the great competition among the nations. It is asserted that such schools need not be so conducted as to abrogate the principle just stated. The State of Massachusetts is already systematically encouraging the organization of textile schools, for example. It is such schools as these that have made Germany what she is, industrially.

Supplementary schools for workers are commended, such as evening schools, correspondence schools, etc. Proprietary and public and Y. M. C. A. evening schools, for example, are doing an immensely valuable work, and these schools cannot be too generally encouraged and sustained. Professor Higgins proposed 'half-time' school is thought well worthy of trial and is considered to have great promise. The higher schools of commerce and of business, which have been organized in some of our colleges already, are thought to be a step in the right direction.

The report is assumed to be preliminary and is to be later supplemented by special discussions of details and of special forms of industrial education. On the whole it would appear that the committee feel as did one of the gentlemen taking part in the discussion, Mr. Rothwell, said: "greater results can certainly be secured by educating the masses than in educating the small number in the higher departments of engineering"; although, as the same speaker remarked: "Nothing can be said against that." As Mr. Fay, of Rhode Island, put it, in his report to the State Legislature, 1877, the great problem is 'that of the adaptation of industrial education to our existing systems of mental training in the public schools,' and in this the committee is also agreed. The committee and the disputants seem to have substantially agreed with Col. E. D. Meier, who asserted that 'the point that the better part of the man should be educated is met by an education based upon the natural sciences'—after the manner advised by Huxley, we may presume.

R. H. Thurston.

* In the State of New York, it may be observed, while the State college, Cornell University, has a proportionally large body of mechanical engineering students and a relatively small body of agriculturalists, the latter, through its 'university extension work,' is performing an enormous task. It sent out in the year 1899–1900, over 7,000,000 pages of bulletins to farmers, embodying results of research in agricultural science and arts; it taught classes of 20,000 in 'Farmers' classes,' 25,000 in its 'Teachers' courses,' 35,000 in its 'Junior Naturalists' Clubs' and 2,500 in 'Home Nature Study,' a total of 83,000 students outside of the university.—President Schurman's Report, 1899–1900.

A Text-Book of Histology, including Microscopic Technic. Authorized Translation of the Second German Revised Edition of DR. BOEHM and VON DAVIDOFF'S Histology. Edited with Extensive Additions to Text and Illustrations by C. CARL HUBER, M.D., of the University of Michigan. Published in Philadelphia by W. B. Saunders & Co. 1900. Price, $3.50, *net.*

In selecting Drs. Boehm and von Davidoff's 'Text-Book of Histology' for an English edition, the American editor has made a happy choice. The excellent features of the original German editions are too well known to need any extensive comment here.

In general plan, clearness and brevity of treatment, combined as a rule with sufficient detail, the text is admirable. The illustrations are for the most part quite good. Especially praiseworthy are the suggestions as to technical methods following each topic, and the references to literature in the back of the book. The student finds here an exceptionally valuable addition to the statements of the text, in the effects of reagents and other treatment of the structures described, and is led to understand how and by whom the science has been developed. This feature gives a very broad conception of the subject, explains the basis of the facts and conclusions presented, and at the same time makes it easy to confirm and extend them in the laboratory and through the literature.

We find unevenness of emphasis, certain subjects being described in much greater detail than are others, as is usually the case in text-books; but the constant reference to original sources should counteract this, and the book as a whole has certainly been a decided success.

Dr. Huber must be congratulated on his English version of so good a text-book. Taking Dr. Cushing's excellent translation as a basis, the editor has rearranged the text to advantage here and there, and has rewritten and extended a number of topics, greatly improving them. Many new and valuable figures have been introduced. This is especially true of the sections on the structure of ganglia and nerve end-organs, the figures having been taken from Dr. Huber's own papers on the peripheral nerves. The nerve supply of all organs is much more fully treated than in the original. The discussion of the development of bone is much improved, and the sections on the structure of the spleen and ductless glands receive considerable additions.

The changes or additions of the editor seem well considered, wherever made, and it is only to be regretted that he has not attempted to bring all sections symmetrically up to date.

Finally the publishers must be complimented on a handsome book with excellent press-work, and with illustrations as good as those of the German edition, which is high praise.

It is a pleasure to cordially recommend this book as one of the very best text-books available on the subject.

SCIENTIFIC JOURNALS AND ARTICLES.

IN the November-December number of the *Physical Review*, Mr. Frank Allen describes an interesting series of experiments to determine the effect upon the persistence of vision of exposing the eye to light of various wave-lengths. It is found that prolonged exposure to red light increases the persistence of vision for light from the red end of the spectrum, while the sensitiveness of the eye for other colors is unaffected. It has previously been shown by Ferry that a 'red-blind' eye shows abnormally great persistence of vision at the red end of the spectrum. In respect to the duration of impressions, therefore, as well as in other respects, an eye that has been fatigued by red light re-

sembles temporarily the eye of a red-blind individual. In like manner temporary green blindness and violet blindness may be produced by fatiguing the eye with light of the corresponding color. Very remarkable results are obtained when the eye is fatigued, not by exposure to one of the fundamental colors of the Young-Helmholtz theory, but by an intermediate color, such as yellow or blue. In case yellow light is used it is found that the persistence of vision is increased for both red and green: *but that the persistence of vision for yellow light remains unchanged.* The article contains much that is of great significance in connection with theories of color vision. In the same number of the *Review*, Dr. W. P. Boynton, of California, discusses the Gibb's 'Thermodynamic Model in the case of a substance obeying Van der Waal's Equation'; while Dr. J. C. Shedd, of Colorado College, gives an analytical discussion of the various forms of curves that are presented by the fringes seen in the Michelson interferometer.

SOCIETIES AND ACADEMIES.

NEW YORK ACADEMY OF SCIENCES.

SECTION OF BIOLOGY.

THE regular monthly meeting for December was held on the evening of the 10th, Professor C. L. Bristol presiding.

Professor Lloyd offered his resignation as Secretary of the Section, on account of his intended absence in Europe. On the motion of Professor Wilson, seconded by Dr. Calkins, a vote of thanks was tendered to the Secretary for his interest in furthering the work of the Section.

The following program then was offered:

G. N. Calkins: 'Some interesting Protozoa from Van Cortlandt Park.'

H. E. Crampton: 'Elimination in Lepidoptera.'

E. B. Wilson: 'The Chemical Fertilization of the Sea Urchin Egg.'

Dr. Calkins stated that there were fonr genera of Protozoa which are usually regarded as intermediate forms between the classes of Protozoa were considered. These were: *Nuclearia*, intermediate between the Rhizopoda and the Heliozoa; *Mastigamoeba*, intermediate between Mastigophora and the Rhizopoda; *Multicilia*, intermediate between the Mastigophora and Ciliata, and *Actinobolus*, intermediate between the Ciliata and the Suctoria. The method of feeding in the latter form was also described for the first time. All these forms, together with 54 other genera and a great many species (100 to 150) were found in the waters of Van Cortlandt Park during the past fall.

The paper by Dr. Crampton was designed to be the first of a series dealing with the problems of variation and selection in Lepidoptera, and especially in the Saturnid moths. The particular questions here considered are as to the relative variability of eliminated and surviving pupæ and moths of *Philosamia cynthia*, and as to the relative variability of males and females. From a lot of 1,090 cocoons from a restricted locality, 310 living and 632 dead pupæ were obtained, the remainder being shriveled or abnormal larvæ and pupæ. The living pupæ were compared with an equal number of dead pupæ in reference to certain body-characters (length, length of bust, width, depth, frontal stature and sagittal stature of bust), and to certain characters of a typical organ, the left antenna (length, breadth and stature). It appears that the surviving males are slightly less variable than the eliminated males, and that the surviving females are far less variable. From the living pupæ 180 perfect moths were obtained. The males were from pupæ which were far less variable than pupæ producing abnormal moths; but the females were from relatively more variable pupæ, though the latter were much less variable than eliminated female pupæ of the preceding group. The paper will be published in full.

Professor Wilson presented the results of a study of the phenomena of development in the unfertilized eggs of *Toxopneustes* when treated with solutions of magnesium chloride by Loeb's method. The results confirm Loeb's conclusion that the embryos arising from these eggs are produced without fertilization by spermatozoa, conclusive proof being given in the fact that during cleavage the number of chromosomes is half the usual number, namely 18 instead of 36. The mitotic phenomena differ in many de-

tails from those occurring in fertilized eggs, but show a striking general parallel to them. The asters may be only two in number (cleavage asters), but as a rule there are many other asters (cytasters) that have no connection with the nucleus. Like the nuclear asters, however, the cytasters contain centrosomes and may progressively multiply by division. Cytasters and centrosomes are formed also in enucleated fragments obtained by shaking unfertilized eggs to pieces before treatment by the magnesium solution, and these asters may likewise multiply by division.

These facts seem to leave no doubt of the formation of functional centrosomes *de novo* and independently of the nucleus. Evidence was adduced to show that the asters may operate as centers of cytoplasmic division, independently of the necleus. It was also shown that the magnesium eggs show numerous gradations in the mitotic process between complete division and partial mitosis.

FRANCIS E. LLOYD,
Secretary.

ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of the Academy of Science of St. Louis of December 17, 1900, forty-six persons present, the following subjects were presented:

Dr. O. Widmann read an account of the great St. Louis crow-roost, in which were embodied many facts concerning the life-history and habits of the common crow.

Professor F. E. Nipher gave an account of some of his recent results in positive photography. He has now found that hydrochinone baths of normal strength may be used. The formula given in each box of Cramer plates yields good results, if the mixed bath is diluted with water to one-third strength. The potassium bromide may be left out, and one drop of concentrated hypo solution must be added for each ounce of diluted bath. The hypo has a most wonderful effect. With the same bath, plates may be developed as positives, in the dark room or in direct sunlight. He had even started the developing of a plate in a dark room, where it progressed very slowly, but satisfactorily; continued the operation in diffused daylight in an adjoining room, and finished the operation in direct sunlight. The process was accelerated by the light, but did not appear to be otherwise changed by the change in illumination. The resulting picture could not be distinguished from those produced by ordinary methods. This picture was shown by means of the lantern.

A box of Cramer's 'Crown,' 'Banner' or 'Isochromatic' plates may have the plates individually wrapped in black paper, in the dark room or at night, and all the remaining work may be done in the light. A plate is taken from its wrapping into the lighted room and placed in the slide holder. After exposure it is taken out into the light and placed in the developing bath, and the picture is then developed in the light, and may be fixed in the light. Of course, during the changes the plate should be shielded from the light as much as is feasible, and the fixing bath may always be covered. But all the operations may be carried on without any dark-room conveniences that may not be secured even in the open fields.

When weak hydrochinone baths are used, the picture, when developed in strong lamp-light, or in sunlight, has at first a golden-yellow color. When left in the lighted bath for an hour and a half, it slowly darkens to a nearly normal shade, as the details come out more sharply. If the exposure has been correctly made, there will be no trace of fog. With stronger baths, the picture comes out in the normal time, and has the normal shade.

If the pictures are too dense, the remedy is to reduce the strength of the sodium carbonate solution, or to increase the amount of hypo in the bath. Very fine results are obtained with the sodium carbonate solution at half the strength given in Cramer's formula.

When the plate has been sufficiently exposed, a negative of the object can usually be seen upon the plate before development. With long exposure this image is very distinct. It fades out in the bath, and the plate becomes clear. The shadows appear strongly but indistinctly at first, and of a pink color, and the high-lights still appear white. The solution remains clear. Too much hypo will cause turbidity and a loss of detail.

When the plate is exposed in a printing frame

under either a negative or a positive, an exposure of half a minute to diffuse daylight is ample, with an ordinary negative. The plate may be over-exposed by placing it for a long time in direct sunlight, and it will then appear on development somewhat like an over exposed negative. This has not yet been tried with hypo in the bath.

Professor Nipher showed a preliminary diagram in which exposure and illumination of the developing bath were taken as coordinates. The zero condition was represented by a line, and the conditions for producing direct and inverted pictures were represented by areas.

He also exposed and developed, in a common bath, in the lighted audience room, negatives printed from negatives and positives printed from positives.

The possible value of radio-active substances acting upon the developing plate in place of or in addition to light was referred to as a most promising field for study.

Professor Nipher stated that he had done no work with the plates of other makers, since he found on trial that one such plate did not give good results with the treatment that had succeeded with the Cramer plates.

One person was elected to active membership.

WILLIAM TRELEASE,
Recording Secretary.

ZOOLOGICAL CLUB, UNIVERSITY OF CHICAGO.

THE first meeting of the Quarter, October 17th, was devoted to a paper by Miss Mary Hefferan, giving the results of her researches on the variation of the teeth in the jaws of *Nereis*. This paper will appear elsewhere in full.

At the second session of the club, October 31st, Mr. R. S. Lillie gave an account of some experimental work upon the reactions of Arenicola-larvæ which was carried on by him during the last summer at Woods Holl. The following is a brief abstract of Mr. Lillie's paper:

In the swarming stage (in which three setigerous trunk segments are present) the larvæ are positively heliotropic and negatively geotropic, and in consequence collect at the surface of the water on the light side of the dish. After the fourth segment has appeared the cilia are lost, the larvæ settle to the bottom, and the heliotropism becomes negative. The heliotropic response is due to the rays at the blue end of the spectrum, the red rays being apparently inactive.

The normal reactions of the swarming larvæ are altered under the following artifically induced conditions: (*a*) rise of temperature of the sea-water, (*b*) dilution or concentration of the sea-water within certain limits, (*c*) alteration of the chemical constitution of the medium. Rise of temperature above 35° is followed by loss of heliotropism and a gradual settling of the larvæ to the bottom; on cooling, however, heliotropism and negative geotropism largely appear. In dilute or concentrated sea-water the heliotropism in a large proportion of larvæ is altered from positive to negative; the same happens in slightly acidulated sea-water (though the effect here soon passes off and positive heliotropism reappears) and also in artificial solutions containing NaCl, $CaCl_2$, and $MgCl_2$ in certain proportions.

Solutions of different salts affect ciliary and muscular movements in definite and characteristic ways. A fact of particular significance is that in the same solution one form of motility may be affected very differently from the other. Pure 5/8n NaCl solutions immediately arrest ciliary movement and cause a liquefaction and dissolution of the cilia; towards muscular movement its action is decidedly less injurious. The poisonous effect of the pure solution is, however, diminished by dilution, and also by the addition of small quantities of other salts, especially $CaCl_2$ and $MgCl_2$. Solutions containing *two* salts in favorable proportions preserve ciliary and muscular activities for considerable periods, each form of activity having its own characteristic optimum solution which differs from that of the other. Pure $CaCl_2$ solutions and pure $MgCl_2$ solutions, and their mixtures, quickly arrest muscular activity and cause the larvæ to become perfectly rigid within a few minutes; while ciliary movement may continue in these solutions in some cases for hours after muscular movement has ceased. The larvæ, although capable of swimming about actively in these solutions, quickly lose all power of heliotropic orientation as their power

of muscular movement disappears; and in a short time they become collected in small groups or clumps, as a result of their inability to effect the muscular movements necessary to disengage them from the contact and adhesion of other larvæ. The fact that ciliary activity can continue (in some cases for many hours) in solutions in which all muscular movement is impossible, proves that these two forms of contractility are essentially very different.

Solutions containing *three* salts in suitable proportions are much more favorable than those containing only two. In solutions of the composition 40 cc. 5/8n NaCl + 55 cc. 10/8n $MgCl_2$ + 5 cc. 10/8n $CaCl_2$, larvæ may remain living and capable of growth for so long a period as two weeks. Mixtures of the above three salts are the most favorable; the presence of KCl is injurious since potassium acts as a specific poison on muscular tissue. The three most essential metallic ions for the life-activities of these organisms are apparently Na, Ca, and Mg; K in very small proportions is probably also necessary.

On analysis of the normal swimming movements of the larvæ it appears that ciliary and muscular movements play separate and independent parts. Propulsion is effected exclusively by the action of the cilia, while heliotropic orientation is a purely muscular phenomenon with which the cilia have nothing directly to do. That this is so is proved (1) by direct observation, which shows that the cilia never exhibit a greater degree of activity on one side of the body than on the other, while the muscles of the more strongly illuminated side always show stronger contractions than those of the other; (2) by the fact of heliotropic orientation of the larvæ in later stages after the cilia have disappeared; and (3) by the fact that all power of heliotropic response is lost in solutions that remove muscular contractility without at first interfering with ciliary movement.

C. M. Child,
Secretary.

ZOOLOGICAL JOURNAL CLUB OF THE UNIVERSITY OF MICHIGAN.

The meetings of November 6th and November 13th were occupied by Dr. H. S. Jennings with an account, accompanied by demonstrations, of his researches on the activities of unicellular organisms. By means of the arc light, stereopticon and projecting microscope, with an intervening alum cell to cut out the heat, the living organisms were projected on the screen, and their reactions to various stimuli could be observed by those present. *Paramecium* thus appeared three inches long, and its minute structure, even to the cilia, was visible.

The collecting ('positive chemotaxis') of *Paramecia* about a bubble of CO_2 and in solutions of mineral acids was shown; also the spontaneous collections formed by the organisms, owing to the presence of CO_2 excreted by themselves. 'Negative chemotaxis' toward salt solutions was shown in the same way. Attention was then directed to the mechanism of the reactions, and it was pointed out that there was no orientation of the organisms either in collecting in the acids or in the negative reaction to salts. By throwing on the screen a slide of *Paramecia* with a small ring marked on the outside of the cover-glass, it was shown that in their swift roving movements at least ten *Paramecia* per second crossed this ring; hence that if any method could be found of keeping in the ring those that crossed it by chance, the area would soon swarm with the *Paramecia*. A drop of weak acid was now introduced beneath the marked ring; it could then be observed that the animals swam into the area just as before, but that on coming to the outer boundary of the area, they were turned back. Hence every *Paramecium* entering by chance remained in the area—swimming rapidly from one side to the other—and in a short time a dense collection was here formed ('positive chemotaxis').

To show the exact mechanism of the reactions, an organism having a more differentiated structure, so that its movements could be more easily followed, was thrown on the screen. For this purpose *Oxytricha* was used. The differentiation of right and left sides in this infusorian was pointed out; then as the individuals approached a source of stimulus, the lecturer predicted, by pointing, in which direction the animal would turn on arriving at the stim-

ulus. The predictions were always fulfilled, since the animals always turn to their right when stimulated.

In the same way *Paramecia* always turn toward the *aboral* side when stimulated. These animals have thus a definite 'motor reaction' to almost any stimulus—consisting of a dart backward and a turning toward a *structurally defined* side. The collection of the *Paramecia* in the drop of acid is due to the fact that the passage from the acid to the water acts as a stimulus to produce this 'motor reacton.' This prevents them from leaving the acid, and a dense collection is soon formed.

The collecting of *Chilomonads* in acetic acid was shown. The essential identity in character of 'positive chemotaxis' or 'positive chemotropism' with 'negative chemotaxis' or 'chemokinesis' was demonstrated by showing that whether we get the one or the other depends on the relative arrangement of the two fluids. If the *Paramecia* or *Chilomonads* were in water, and a drop of acid was introduced, a dense group was quickly formed in the acid ('positive chemotaxis'); if on the other hand the organisms are in acid and a drop of water is introduced, the latter remains quite empty. If now the organisms were in water and a drop of salt solution was introduced, the drop remained empty ('negative chemotaxis,' or 'chemokinesis'); if the organisms were in salt solution and a drop of water was introduced, they swarmed into the drop of water, as previously into the acid. Passage from the water to acid does not cause the 'motor reaction,' while passage from the acid to the water does, hence they collect in the acid; passage from the salt solution to the water does not cause the reaction, while passage from the water to the salt does, hence they collect in the drop of water.

Many other demonstrations were given, and the significance of the results in simplifying the 'psychology' of these organisms, and in their relation to current theories of tropisms or taxis was discussed. Similar results to those set forth were stated to have been obtained with certain Metazoa also.

H. S. JENNINGS,
Secretary.

DISCUSSION AND CORRESPONDENCE.

UNAUTHORIZED NEWSPAPER REPORTS.

IN view of the fact that a number of daily papers have printed reports concerning alleged or real experiments of mine I wish to state:

1. That none of the statements printed in the newspapers have been authorized by me.

2. That whatever I may have to say about my work will be published in scientific journals.

JACQUES LOEB.
UNIVERSITY OF CHICAGO.

AN APPEAL FOR ASSISTANCE.

TO THE EDITOR OF SCIENCE: A letter received from Mr. R. W. Garner, dated from Sao Thomé, West Africa, November 26, 1900, gives rather painful news of that intrepid explorer in the jungles of West Africa. Relying upon his remarkable powers of endurance and his simple habits of life, Mr. Garner started on this expedition with very limited means and an inadequate outfit. It seems that on this occasion he was overcome by the jungle fever, and the unexpected expense incurred by a month's sickness has exhausted his resources. He does not ask for help, but states that since he is already in a country where few men would care to venture, it seems as if some institution might like to send him a moderate sum of money, in return for which he would collect ethnological and zoological material, and at the same time could continue his own investigations. This is certainly a good opportunity, and any institution that can take advantage of it would at the same time be rendering assistance to a worthy explorer who is deserving of help in his undertaking. It will be necessary to secure Mr. Garner's services at once, since it is evident that if he does not receive some substantial cooperation, he cannot continue his researches. Any communication should be sent direct to Mr. R. W. Garner at Sao Thomé, West Africa.

F. W. PUTNAM.
PEABODY MUSEUM OF ARCHEOLOGY AND ETHNOLOGY, HARVARD UNIVERSITY, CAMBRIDGE, MASS.

CURRENT NOTES ON METEOROLOGY.

RAINFALL OF NEW SOUTH WALES.

THE 'Results of Rain, River, and Evaporation Observations made in New South Wales

during 1898,' compiled by H. C. Russell, Government Astronomer of New South Wales, show that the year 1898 is to be classed as a drought year, and was the fourth of that character to follow in succession. The average rainfall of the Colony for the year was 20.54 in., as against an average rainfall, derived from 28 years' record, of 24.85 in. The heaviest average rainfall, 64 in., is found on the Tweed river, just at the foot of a range of mountains from 4,000 to 6,000 feet high, against which the trade winds blow. A hopeful view is taken by Mr. Russell regarding the possibility of long range weather forecasts in New South Wales. "I am fully convinced," he says, "that a complete record of the rainfall will enable us to forecast the seasons with some show of success, provided, of course, that the extended knowledge of our rainfall is concurrent with a careful study of Australian and tropical weather, which is now in progress. * * * Further study will, there is reason to expect, explain the reason for dry years and when to expect them."

RAINFALL AND ALTITUDE IN ENGLAND.

The *Quarterly Journal* of the Royal Meteorological Society, for October, contains a paper by Marriott on 'Rainfall in the West and East of England in Relation to Altitude above Sea-Level,' in which the mean annual and monthly rainfalls at the English and Welsh stations are discussed for the ten-year period 1881–1890. The stations are classed as 'eastern' and 'western,' the former being those that drain to the east and the latter those that drain to the west. A further classification was made according to altitude, the stations being grouped together for each 50 ft. up to 500 ft., and above that altitude for each 100 ft. The increase of rainfall with altitude may be compactly summarized as follows:

100 feet	+ 9	per cent.	600 feet	+ 5	per cent.
200 "	+ 3	"	700 "	+38	"
300 "	+ 3	"	800 "	+ 3	"
400 "	+14	"	900 "	+ 4	"
500 "	+ 1	"	1000 "	−21	"

A NEW METEOROLOGY.

A new 'popular' presentation of the essential portions of meteorology, within the compass of a small octavo volume of 123 pages, at a cost of 80 Pfennige (20 cents) comes in a recent mail from Germany. This little book is by Paul Kaegbein; is entitled 'Meteorologie'; appears in the *Wissenschaftliche Volksbibliothek;* is published by Schnurpfeil, of Leipzig, and can really be recommended as giving a good general view of the subject with which it deals. The price is certainly low for the amount of information contained in the book. One of the chief objections to the book is the fact that the author has drawn largely on some of the standard works on meteorology, such as Hann's *Handbuch der Klimatologie;* Abercromby's *Weather*, etc., without acknowledging his indebtedness to the writers from whom he obtained his material.

ATLAS OF THE INDIAN OCEAN.

The Royal Meteorological Institute of the Netherlands has recently issued a meteorological atlas of the Indian Ocean for the month of June, July and August. The two preceding volumes for the months of December, January and February, and March, April and May, respectively, preceded the present volume by seven years. The charts contained in the third part of this important publication are stated in the preface to have been ready in September, 1899. There are in all twenty-two charts, showing surface temperatures of the ocean water; ocean currents (velocity and direction); pressure; air temperature; winds (by means of wind roses); rainfall (in percentages); the distribution of thunder, fog, hail, cloudiness; the average limits of whales, flying fish, etc.; the sailing routes; percentages of storm frequency, and the trajectories of cyclones.

R. DeC. Ward.

---

*THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.**

At the International Conference which met in London last June to discuss this subject, it was thought that the time had arrived when the great work of publishing a complete catalogue of all the scientific literature of the world might be undertaken with every prospect of success.

A Provisional International Committee was, therefore, appointed at the Conference to carry

* From *Nature*.

out the preliminary work, and this Committee reported the results of its labors to an International Council which met last week in the rooms of the Royal Society.

At this meeting, which took place on December 12th and 13th, there were present: Professor B. Schwalbe, representing Dr. Milkau (Germany), Professor G. Darboux, representing Professor H. Poincaré, and Dr. J. Deniker (France), Professor A. W. Rücker, Sir M. Foster, Professor H. E. Armstrong and Dr. L. Mond (Great Britain), Professor J. H. Graf (Switzerland), Dr. E. W. Dahlgren (Sweden), Professor Korteweg (Holland), Dr. M. Knudsen (Denmark), Mr. Roland Trimen (Cape Colony), Dr. W. T. Blanford (India), Señor del Paso y Troncoso (Mexico), and M. Metaxas (Greece). Dr. Ludwig Mond represented Italy in the absence of Profesor Nasini. Sir Michael Foster was elected chairman of the meeting.

It is proposed that the annual cost of a set of seventeen volumes shall be 17*l.*, and on this basis it was announced that the number of sets subscribed for by the various countries was as follows:

United States of America	68
Great Britain	45
Germany	45
France	35
Italy	27
Japan	15
Switzerland	7
Sweden	6½
Denmark	6
Holland	6
Norway	5
Mexico	5
Cape Colony	5
Canada	4½
Hungary	4
Portugal	2
South Australia	2
Western Australia	1
Victoria	1

One great difficulty in starting an enterprise of this magnitude is that a large amount of capital is needed to cover the preliminary expenses and to pay for the printing of the first set of volumes, and for other work which must be done before the grants from the various countries are received, and before any sales of the volumes to the public can be effected. This initial difficulty was met by the Royal Society, which generously offered to advance the necessary capital. This offer was accepted by the International Council, which expects to be in a position to repay the sum advanced during the next few years.

The Royal Society offered to act as the publishers of the catalogue, and to sign the necessary contracts with the printers and publishing agents. This offer was unanimously accepted by the International Council, which, after carefully examining the clauses of the proposed contracts, declared its approval of them.

The three principal countries which have not yet joined in the scheme are Russia, Belgium and Spain; and the Royal Society was asked by the International Council to address the Imperial Academy of Sciences of St. Petersburg on the subject, and also to take steps to induce the other countries to join in the catalogue.

A code of instructions for the use of all who are taking part in the preparation of the catalogue was considered, and, after some amendment, adopted.

In this connection the chief point discussed was whether it is desirable to publish complete lists of new botanical and zoological species. It was decided that lists of new species should be published, and that they should, as far as possible, contain all the additions to our knowledge in this direction made within the year.

It was also decided to include translations in the catalogue, but to indicate that they are translations. Schedules of classification for the subject indexes of the several sciences were adopted.

An executive committee was appointed, consisting of the four delegates of the Royal Society and the representatives of the four largest subscribers to the catalogue—France, Germany, Italy and the United States. Dr. H. Forster Morley was appointed director of the catalogue.

Finally, it was resolved to begin the work on January 1, 1901, and to include in the catalogue all literature published after that date.

SCIENTIFIC NOTES AND NEWS.

DR. H. C. BUMPUS, professor of comparative anatomy at Brown University and director of the Biological Laboratory of the U. S. Fish Commission at Woods Holl, has been appointed curator of invertebrate zoology and assistant to

the president in the American Museum of Natural History, New York City. The office of assistant to the president, Mr. Morris K. Jesup, is an important executive position, as the Museum has no scientific director. It was created last year and was filled by Professor H. F. Osborn, who has resigned in order to devote himself more exclusively to research in vertebrate paleontology.

A FURTHER reorganization of the staff of the American Museum of Natural History has been made. A department of mineralogy has been formed, with Dr. L. P. Gratacap as curator, while R. P. Whitfield remains curator of geology, with Dr. E. O. Hovey as associate curator. Professor Franz Boas and Dr. Marshall H. Saville have been made curators, the former of ethnology and the latter of Mexican and Central American archeology, though Professor F. W. Putnam retains the head curatorship in the department of anthropology. In the department of mammalogy and ornithology, Mr. Frank M. Chapman has been made associate curator.

AT a meeting of the Paris Academy of Sciences on December 17th, announcement was made of the great number of prizes annually awarded. The Janssen gold medal was conferred on Professor E. E. Barnard for his discovery of the fifth satellite of Jupiter, and the Cuvier prize was awarded to Professor Anton von Fritsch, of the University of Prague.

M. PAINLEVÉ has been elected a member of the section of geometry of the Paris Academy of Sciences.

THE Elisha Kent Kane medal of the Geographical Society of Philadelphia, has been presented to Dr. A. Donaldson Smith, the African explorer.

DR. ANITA NEWCOMB MCGEE has resigned her position as acting assistant-surgeon, U. S. A., after having organized 'The Army Nurse Corps.' In accepting the resignation Surgeon-General Sternberg writes:

"I desire to express to you my high appreciation of the valuable services you have rendered during the past two and one-half years in selecting trained female nurses for duty at our field and general hospitals wherever their assistance has been necessary, and in organizing the 'Army Nurse Corps' upon a satisfactory basis. You have shown excellent judgment and executive ability and have labored zealously both in the interest of the nurses and of the Government."

IT is proposed to erect a monument in memory of the late Professor Camara Pestana, who fell a victim to his devotion to scientific research in the recent epidemic of plague at Oporto.

MONEY is being collected for a heroic bust of the late Professor Thomas Egleston, 'Founder of the School of Mines' of Columbia University, in 1864. The work of modeling has been intrusted to the sculptor, William Couper.

THROUGH the courtesy of Mrs. Joseph Leidy, Jr., of Philadelphia, a life-size oil painting of the late Dr. Joseph Leidy, fellow of the College of Physicians, president of the Academy of Natural Sciences and professor of comparative anatomy and biology at the University of Pennsylvania, has been presented to the College of Physicians.

THE death is announced, on December 25th, at Vineland, N. J., of Professor N. B. Webster, founder and for many years head of the Military Institute at Norfolk, Va. He was also a lecturer on scientific and educational topics. Professor Webster was a fellow of the American Association for the Advancement of Science, having been elected a member in 1853 and a fellow in 1874.

LORD WILLIAM GEORGE ARMSTRONG, inventor of the gun that bears his name and of hydraulic machinery, and the author of numerous scientific articles, died on December 27th. He was born in 1810, was elected a fellow of the Royal Society in 1843 and was president of the British Association in 1863. Lord Armstrong was knighted in 1858 and raised to the peerage in 1887.

THE death is announced of Dr. William King, for thirteen years connected with the Geological Survey of India, and for seven years its director.

MICHEL-EDMOND BARON DE SELYS-LONGCHAMPS, an eminent entomologist and a high authority on Odonata, died at Liège on December 11th, in his eighty-seventh year.

SIR JOHN CONROY, F.R.S., formerly lecturer in physics and chemistry in Keble College, Oxford, died at Rome on December 15th.

THE Honorable David Carnegie, assistant resident commissioner for the British Government in West Africa, known for his explorations in Central Australia, has died from a wound made by a poisoned arrow.

THE death is announced of the Portuguese explorer, Major Serpa Pinto, at Lisbon, at the age of fifty-four years. Beginning in 1877, he crossed Africa from Benguella to Durban and published a book on his expedition.

WE regret also to record the following deaths among men of science abroad: Dr. S. J. Korschinski, the botanist, of St. Petersburg; Dr. Richard Altmann, assistant professor of histology in the University of Leipzig; Dr. E. Ketteler, professor of physics in the Münster Academy; Dr. Walter von Funke, formerly professor of agriculture in the University at Breslau, and Dr. Hermann Stechmanns, director of the zoological gardens in Breslau.

THE meeting of naturalists at Chicago during the Christmas holidays was very successful. Besides the discussion on 'State Natural History Surveys: Methods, Results, Cooperation,' in which Professors Birge, Nachtrieb, Smith, Eigenmann, Conway MacMillan, Cowles and others took part, about forty papers were read. A zoological and a botanical section were formed to receive the papers of more special interest. Over one hundred persons were in attendance. There were forty-one at the dinner. No permanent organization was effected. The following were appointed a committee on a meeting for next year: Professor S. A. Forbes, University of Illinois, *President;* Professors D. M. Mottier, University of Indiana; W. A. Locy, Northwestern University; Conway MacMillan, University of Minnesota, and C. B. Davenport, *Secretary.*

THE Association of American College Physical Directors held its annual meeting at Columbia University, New York, on December 29th and 30th. A number of papers relating to physical training and anthropometry were presented and discussed. Dr. R. Tait McKenzie, of McGill University, was elected president for the ensuing year.

THE Duke of the Abruzzi proposes to start from Buenos Ayres in 1902 on a voyage to explore the South Polar Seas. A ship is to be built in Italy for the purpose.

DR. F. A. COOK, who, it will be remembered, was a member of the Belgian South Polar expedition, has sailed for Europe to cooperate in the preparation of the account of the expedition which will be published in ten volumes.

MR. E. B. BALDWIN has purchased for his proposed Arctic expedition the *Esquimaux*, said to be the largest and staunchest of the British whaling fleet.

THE collection of minerals and meteorites, made by Mr. Clarence S. Bement of Philadelphia, has been acquired by the American Museum of Natural History, New York. This is a collection of much importance and will be described in a subsequent issue of this JOURNAL.

DR. EDWARD EVERETT HALE has recently given the Semitic Museum at Harvard University a collection of Egyptian antiquities, consisting of bronze, stone and terra cotta statuettes, vases and lamps, collected by Dr. Hale's brother, Charles Hale, while a United States Consul in Egypt.

MR. THEODORE MARBURG, of Baltimore, a well-known art collector, has presented to Johns Hopkins University a collection of antiques from the Island of Cyprus.

WE learn from *Nature* that the Botanical Department of the British Museum has recently acquired M. Bescherelle's herbarium of exotic Musci and Hepaticæ, consisting of 14,800 specimens of the former and 3,500 of the latter family. It contains a very large number of type-specimens.

THE sum of 10,000 crowns has been given by the King of Sweden and Norway to assist the archeological researches of Dr. L. Kjellberg in Asia Minor and the island of Lesbos.

SENATOR HANSBROUGH introduced on January 4th a bill creating a department of education, the head of which is to have a place in the cabinet.

THE daily papers report that Governor-Gen-

eral Wood has, in view of the probability that mosquitoes are concerned in the spread of yellow fever, issued orders for the use of mosquito netting in barracks and hospitals and on the field where possible, for the use of petroleum on temporary pools and for filling up permanent pools.

THE *British Medical Journal* reports that Professor Celli, who is a member of the Italian Parliament, will introduce drastic measures for the suppression of malaria in Italy. He would make punishable by law the neglect of landowners and all employers of labor to provide in malarial districts every means of fighting the the fever. Bosselli and Sonnino have proposed that the Minister of Finance purchase pure quinine and sell it to the public at a slight advance over cost. The profit could be applied to the extermination of malaria.

UNIVERSITY AND EDUCATIONAL NEWS.

AN influential meeting was held at San Francisco, on December 22d, to advocate the passage of an inheritance tax law in aid of the State University.

THE late Chief Justice Faircloth, of North Carolina, bequeathed $20,000 to the Baptist Female University of Raleigh.

WE regret to learn that the will of the late George V. Clayton, giving about two and a-half million dollars to the city of Denver for the establishment of a college for poor boys, is being contested by a brother.

THE great Hydraulic Laboratory of Cornell University is nearing completion and will be ready for work early in the spring. In its incomplete condition it has been used for experiments in connection with U. S. Deep Water Ways Commission, also in experiments for the New York State Canals. Investigations have also been made in reference to the water supplies of the City of New York and for the Lake Superior Power Company. Corporations and individuals wishing to make investigations for the benefit of Hydraulic Science or Public Improvements are invited to communicate with the Director of the College of Civil Engineering of Cornell University, Ithaca, N. Y.

GROUND has been broken for the new Hall of Mechanical Engineering, for Syracuse University, and work is being pushed forward in order that it may be in readiness for occupancy by the spring of the next college year. The building will be of stone, four stories above the basement, 133 feet in length, by 60 feet in depth. Its equipment will be thoroughly modern in every detail.

THE report telegraphed from California to the daily papers that President Benjamin Ide Wheeler would this year succeed President Eliot, of Harvard University, is entirely without foundation.

CHANCELLOR WILLIAM H. PAYNE, PH.D., LL.D., of the University of Nashville, Tenn., has been elected to the professorship of the science and the art of teaching in the University of Michigan, vacant by the death of Dr. B. A. Hinsdale. Dr. Payne was Dr. Hinsdale's predecessor in this chair.

H. WADE HIBBARD, A.B., A.M., M.E, formerly connected with the Rhode Island Locomotive Works, Pennsylvania and Lehigh Valley Railroads, has been elected Professor of Mechanical Engineering of Railways, having for the past two years been assistant professor and Principal of the Railway School of Sibley College, Cornell University. This railway course is the latest addition to the several specialized finishing schools which are available for the 670 students in mechanical engineering now registered at Cornell.

DR. ARTHUR ROBINSON, lecturer on anatomy in the Middlesex Hospital Medical School, has been appointed professor of anatomy in King's College, London, in the vacancy caused by the death of Professor Hughes.

DR. FREDERICK GOLTZ, who has occupied the chair of physiology of the University of Strasburg for twenty-nine years, has retired.

AT Trinity College, Cambridge, the Coutts-Trotter studentship for the promotion of original research in natural science, especially for physiology and experimental Physics, has been divided between Charles Francis Mott, B.A., and Owen Williams Richardson, B.A., both scholars of the college. The tenure is until September 29, 1902.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, JANUARY 18, 1901.

CONTENTS:

Annual Discussion before the American Society of Naturalists:—
The Attitude of the State toward Scientific Investigation: PROFESSOR HENRY FAIRFIELD OSBORN, PROFESSOR WM. BULLOCK CLARK, DR. L. O. HOWARD, DR. B. T. GALLOWAY, PROFESSOR WILLIAM T. SEDGWICK 81
The Albany Meeting of the Geological Society of America (I.): PROFESSOR J. F. KEMP 95

*ANNUAL DISCUSSION BEFORE THE AMERICAN SOCIETY OF NATURALISTS.**

THE ATTITUDE OF THE STATE TOWARD SCIENTIFIC INVESTIGATION.

A FAIR criterion of intelligence in the government of a country is afforded by an examination of its annual budget. There is first the provision for a certain number of expenditures which are purely conservative, because the State must maintain itself, it must defend itself, it must support a large class of office holders who are more or less useful. Without knowing the figures it is safe to say that the budget of Russia is chiefly of this order. These expenditures may be wisely and honestly made, but they largely go to waste; they are either immediately productive or altogether non-productive. On the other hand, there are expenditures in the nature of investments, looking to the future and characterizing the most far-sighted statesmanship. Conspicuous among these are the funds invested in education and science.

Said Helmholtz in 1862†: "In fact men of science form, as it were, an organized army, laboring on behalf of the whole nation, and generally under its direction and

* Given at the Baltimore Meeting, 1900.

† 'On the Relation of Natural Science to General Science' (Heidelberg, 1862), 'Popular Lectures on Scientific Subjects' by H. Helmholtz. New York, D. Appleton & Co. 1873. Pp. 28–30.

at its expense, to augment the stock of such knowledge as may serve to promote industrial enterprise, to increase wealth, to adorn life, to improve political and social relations and to further the moral development of individual citizens. After the immediate practical results of their work we forbear to inquire; that we leave to the uninstructed. We are convinced that whatever contributes to the knowledge of the forces of nature or the powers of the human mind is worth cherishing, and may, in its own due time, bear practical fruit, very often where we should least have expected it." Helmholtz in this most influential essay enforces his point by citing Galvani and Galileo and continues: "Whoever, in the pursuit of science, seeks after immediate practical utility may generally rest assured that he will seek in vain. All that science can achieve is a perfect knowledge and a perfect understanding of the action of natural and moral forces. * * * At the same time we must acknowledge that the value of scientific discoveries is now far more fully recognized than formerly by public opinion, and that instances of the authors of great advances in science starving in obscurity have become rarer and rarer. On the contrary, the government and peoples of Europe have, as a rule, admitted it to be their duty to recompense distinguished achievements in science by appropriate appointments or special rewards."

Upon the general contention of Helmholtz as to the ultimate practical importance of pure scientific work, Dr. Galloway will speak from the standpoint of botany and Dr. Howard from the standpoint of applied entomology.

Of European countries Germany places in its budget the largest productive investments of this kind; France is not far behind, England is perhaps fourth and affords a conspicuous example of blindness and fatuity in the matter of unproductive investment; she has, it is true, established textile schools, but has not sufficiently supported technical schools; the cost of a single battleship would establish four splendidly equipped technical schools; England secures the ship and postpones the construction of the schools. All this is through no fault of her prophets of science, who have been as persistent as Jeremiah in foretelling the consequences which are sure to follow.

Yet England gave Darwin his schooling upon the *Beagle;* Huxley secured his upon the *Rattlesnake.* As a sea-faring nation marine zoology appeals to her imagination, and the single notable departure from her short-sighted policy in the encouragement of pure science is the magnificent service she has rendered in the *Challenger* expedition. Our own Dana was trained upon the Wilkes expedition; the French Government equipped the *Talisman*; the German government is supporting the highly successful cruise of the *Valdivia* and its publications under Chun; the U. S. Government has a permanent exploring vessel in the *Albatross.*

In this rivalry of foresightedness the German and French governments have been our keenest competitors both on sea and land, and have probably surpassed us in the recognition of the ultimate economy of pure research. In Germany, quite apart from the extension of the technical school system which to-day is placing her in the lead of all the manufacturing states of Europe, one recalls the annual grant to the Naples Zoological Station. Her most admirable recent action is the subvention of Professor Abbe for his investigations upon optics. Abbe's work was not in the nature of invention, but of research and discovery in the highest sense resulting in the production of an illuminating stage, apochromatic and achromatic immersion lenses, which have fairly revolutionized biology. What we owe to these lenses in a theoretical sense could not be stated in a single

volume and the economic value is equally immeasurable.

The distinctive feature of pure science is that it is not remunerative; the practical rewards and returns are not the immediate objects in view. On the other hand, the work of Tyndall and Pasteur on fermentation, pursued in the first instance for its own sake, has come to have an economic importance which is simply incalculable.

American legislators have lent a willing ear to the advice of wise men. What we now enjoy we owe mainly to the counsels of Joseph Henry, Spencer F. Baird and G. Brown Goode. And I may call attention here to a thought which will be expanded presently, namely, that the secret of the success of these men is to be found in their enthusiasm, unselfishness and lofty scientific and personal character. When we consider the liberal appropriations made year after year for the United States Geological Survey, the nobly equipped station at Wood's Holl, the purely scientific work which is now being supported by many States and municipalities, there is abundant cause for congratulation; but lest we think of ourselves more highly than we ought to think, let us recall the contrast between our lavish liberality in certain appropriations and our lack of enlightenment in certain details of legislation. The student steps in line with the farmer to support the manufacturer; he is encouraged to work, he is denied the tools. In regard to the importation of models, microscopes and other scientific instruments the tariff is a tax which bears most heavily upon research. By the tariff on lithographic plates Congress places a Chinese wall around publications of the first class in all branches of natural history. America is a most unfavorable center of scientific publication so far as illustrations are concerned. Professor Sedgwick will perhaps have something to say upon these subjects.

In these matters the American Society of Naturalists has expressed and will continue to express its urgent desire for reforms which will come about through public enlightenment.

The main object of this discussion, however, is not merely a reiteration of opinions which we all share, but a symposium in regard to some of the new directions in which we must apply our energies in order to secure ultimately the best results.

In the last analysis we are *advocating public taxation* for the purposes of research. Having considered the parental relation of the State to the investigator—what are the filial relations of the investigator to the State. Granting that we have carried the outer works by demonstrating the wisdom of taxation, felicitating ourselves upon the fact that we have an enlightened public opinion behind us, there now remains the honorable obligation on our part of administering these funds to the very best service of the State, and it is to this obligation I wish to especially direct your attention. There are two directions in which it is possible that we have not as yet fulfilled our duty.

I believe with Huxley that good science rests upon good morals and that good morals rest upon those principles which are best enunciated for plain people in the ten commandments. In the special field of work under discussion, it seems to me that in return for the confidence of the State, specialists are under the binding obligation to administer public funds in the most scrupulous manner. I have in mind instances where the confidence of the State has been betrayed and where results damaging to the general cause of science have inevitably followed. Extravagance in the use of words and parsimony in the use of ideas; the lavish illustration of papers of little scientific and of less literary value; the reckless expenditure of public funds for instruments, apparatus,

and general equipment that anticipate imaginary rather than real needs; the diversion of these funds to purposes for which they were never intended; the surreptitious introduction of material not mentioned in the original purpose of an appropriation; in short, the obtaining of money under false pretenses; these are immoralities which retard the development and jeopardize the existence of the grand system which our state and national governments have so wisely instituted.

A second consideration is the importance of cooperation between nation, state, and university in education and organization for research. A conspicuous example of the splendid results which may flow from such cooperation is found in the present administration of the United States Geological Survey. We see the Government cooperating with the states and with the universities and public museums to produce a uniform investigation of the geology and paleontology of the entire area of the United States. Of this Professor Clark is far better qualified to speak than I am.

In the foundation of the United States Fish Commission Station at Wood's Holl, Spencer F. Baird, one of the most large-minded men this country has produced, formed a similar conception of the advantages of cooperation in biology, which alone justifies the erection of an enduring monument to his memory. While the execution of his purpose may be described as having ebbed and flowed like the tides, strong under some administrations, such as Goode's, and not even as yet fully attained, we have in the last few years seen an approach to the fulfilment of Baird's ideal, and it remains for the United States Fish Commissioner and his staff, and the Director and Trustees of the Marine Biological Laboratory at Wood's Holl, to consider a plan of cooperation which will effectively combine the intellectual and material forces of these two institutions in the future. No private institution can compete with the material resources of the government; no government institution can flourish without availing itself of the intellectual resources of the university. The cooperative advantages which the Marine Biological Laboratory should enjoy as the premier institution of its kind in this country should be extended to other laboratories along the coast. The difficulties in the way of bringing about such cooperation are more apparent than real, in fact, I am one of those who have firm faith that the ideal is also the practical and that we shall see Baird's plans fulfiled in the case of biology, even as Hayden's plans have been fulfiled in the case of geology.

If the larger scientific interests of the country are one, and if the Utopian state is one in which there is a sympathetic nervous system connecting state and university work, it is obvious that our colleges and universities should consider more carefully than they have done the preparation of men especially for state work. Educators have perhaps had too exclusively in mind the medical school, the teaching profession, and too little the direct service of the state. This is a feature of the general subject which will be especially spoken of by Dr. Howard who is well qualified by his knowledge to discuss present conditions in state and college and the present needs of government science.

College and university men of science, and state and government men of science, naturally acquire certain individual characteristics; they have their strong points and their weak points, and it is of advantage to American science at large that these two classes of men in all departments of science, in physics, chemistry, geology, botany, zoology, should abrade their angles by coming into frequent contact; because contact not only removes prejudices, but it increases mutual respect and admiration,

until an entire unity of purpose and action is consummated which completes the scientific structure of the nation.

HENRY FAIRFIELD OSBORN.
COLUMBIA UNIVERSITY.

THE attitude of the state toward scientific investigation is less a question of inherent right than of expediency. Political economy assigns no sharp limitations to the functions of government and whether or not any particular interest should receive the fostering care of the state depends upon circumstances. That scientific research is a subject of government concern is becoming recognized more fully every year. A well-known English educator in discussing the endowment of research by the state says: 'that liberal and scientific culture, intelligence, and the whole domain of mind, is a national interest, as much as agriculture, commerce, banking or water-supply.'

Granting all this, and I am sure no one here maintains any other view, we are confronted with the fact that the state cannot support, or even subsidize, *every* national interest. Which should receive government support must finally be determined by expediency—by whether in the long run the state is to be benefited by the aid extended.

Agriculture, commerce and banking, for example, can be maintained by private enterprise and can be made largely or wholly self-supporting. Their prosecution can be left therefore largely to the individual, with such incidental protection as may be required in the particular case. Scientific investigation is not and cannot hope to be self-supporting in most instances. This I believe to be the determining factor. Admitting the material value of scientific investigation to the state, it becomes necessary for the state to see that its interests are secured.

It may perhaps be desirable to examine for a moment the reason why scientific investigation is not and can not be self-supporting. This may be found in the fact that the great majority of scientific researches have no immediate commercial value and as commodities can not find a speedy or, in most instances probably, even a prospective market. We all know of many investigations, begun without thought of pecuniary advantage, that have ultimately produced practical results of the greatest importance. Instances might be cited of investigations, the value of which were not apparent until a generation or more had passed, as, for example, paleontological researches which have laid the foundation for the correlation of deposits of great economic value. The support of such investigations must, as Professor Osborn has shown, be looked upon as investments for the state which no far-sighted statesman will ignore.

I have found, although my own experience has been limited to be sure, that the average legislator, who is considering honestly the interests of the state, is not without appreciation of the far-reaching value of scientific work, if convinced that the investigations proposed will be honestly conducted. The legislator, surrounded, as he too frequently is, by evidences of political jobbery of every sort, is very keen in detecting what is false and untrue. He may be over-suspicious in some instances and may even suggest that you have some ax to grind in the measure which you bring forward, but if he is honest in purpose his support in the end is not difficult to obtain. I have always gone on the principle that the legislator whose support I was seeking was a public-spirited and intelligent citizen who was capable of judging of the true merits of the subject under consideration. I have never claimed for the investigation proposed that it would in every instance bring an immediate financial return, but rather that the work laid the foundation for subsequent re-

searches, the material value of which could not be estimated. In stating the objects of the Maryland Geological Survey in the opening chapter of the first volume of its reports I said: "The fact must be borne in mind that much preliminary and fundamental work has to be done, the utility of which is not at once apparent to the uninitiated. The publication of such material, rendered necessary as a basis for future investigation, is often liable to misinterpretation, but yet may be of far more lasting value to the State than some superficial statement that is intended to meet a supposed practical need." I believe it is not difficult for the scientific man, with a subject of real merit, to secure the confidence and support of any body of legislators, if he approaches them with honesty of purpose, and with his plan sufficiently matured for them to see its real significance.

We find that ever since the establishment of universities and seminaries widely over Europe in the fourteenth and fifteenth centuries, the civilized countries of the world have recognized in one form or another the relation of the state to scientific investigation. Not only the great nations of the world but oftentimes the small and relatively poor countries like Belgium and Switzerland, as well as the smallest of our own commonwealths, have frequently provided liberally for the support of scientific research. This has been accomplished through the publicly endowed educational institutions, through the public museums and through the special bureaus of the government. The dependence of these various public organizations, as well as the privately endowed institutions upon one another in scientific investigation, has been already pointed out by Professor Osborn, and I shall presently refer to a concrete instance of this in my own work.

Too frequently scientific investigation has held a subordinate place in both the publicly and privately endowed institutions, their chief functions being either educational or commercial. The purpose of the schools and universities is primarily in most instances the instructing of youth in the already acquired results of scientific research rather than the fostering of investigation for itself, although the latter as a secondary consideration often holds a prominent place in the larger institutions of learning. The museums and scientific bureaus are like our great universities centers of research, without the exactions of teaching, where continuous investigation can be pursued under most favorable conditions, although here again either educational or commercial considerations for the most part ostensibly control. That this is not always the case either in our own country or abroad is cause for congratulation, and the support of research directly for itself without other, and oftentimes false, claims is becoming yearly a more fully recognized fact.

It is interesting for us who are Americans to know that the claims of science received recognition at the very inception of our government, for we find that George Washington in his first message to Congress stated: "Nor am I less persuaded that you will agree with me in opinion that there is nothing more deserving your patronage than the promotion of science and literature. Knowledge in every country is the surest basis of public happiness. In one in which the measures of government receive their impressions so immediately from the sense of the community as ours it is proportionally essential." How well that early advice has been carried out by the statesmen of later days under the wise counsels of Henry, Baird, Goode and their successors, Professor Osborn has already shown.

That much can be accomplished through cooperation between our national bureaus and the State and university institutions, I

have had occasion to know in the conduct of the State Geological Survey of Maryland, the resources of several of the national bureaus, as well as the State and university institutions being at my disposal in the advancement of the work. Any single one of these agencies, if alone employed, could not readily have accomplished the same results. This is shown by the scope of the work which the local scientific bureau in most of our smaller States must necessarily embrace. Its investigations cannot be as fully differentiated as is possible in the case of the national bureaus, except by largely increased expenditure, seldom provided even by our richest States, and whether the organization is known as a geological survey or by some other name, it must naturally deal with the whole realm of the physical features of the commonwealth. It need not, however, encroach upon the functions of other departments of the government and more particularly of its nearest associates, the more strictly agricultural institutions, but should, by the classification and mapping of the soils which depend primarily on geological criteria, afford the foundation for agricultural work. But in this as well as in the topographic, hydrographic, magnetic, climatic and forestry work, the relations of all of which to geology are more or less intimate, the aid of the national bureaus is essential, while the State bureau can be the medium by which the results may be presented to the local communities in a manner that would be difficult if not impossible for any institution of the central government. Each has a well-defined field of action and instead of conflicting can be of material advantage to the other.

The same is true of the university and in even larger degree, for here are trained the specialists, who either in State or in national work can add much to the effectiveness of both, while the opportunities afforded by the latter for wider experience react on the university in many ways. The advantages offered the university instructor and student by cooperation in government explorations and surveys are only part of the increased opportunities which can result from this relationship. The various bureaus and divisions of the U. S. Department of Agriculture, the U. S. Geological Survey and the U. S. Coast and Geodetic Survey are all manifesting a broad spirit of helpfulness that is being met by the state and university institutions. The possibilities of an extension of this cooperation between nation, state and university promise well for the widening of the bounds of scientific investigation in this country. It is indeed a hopeful sign when we see the scientific men of the nation, whatever their affiliations, working together with mutual interest and respect. May it presage the dawn of a still brighter day in American science.

WM. BULLOCK CLARK.
JOHNS HOPKINS UNIVERSITY.

THE State and scientific research cover an enormous field—as broad as scientific research and as broad as government possibilities. The men who have spoken and are still to speak are specialists. They can speak theoretically of other matters, but more authoritatively of their own field. I am a specialist and shall therefore limit myself to 'the State and zoology.' By 'the State' I shall refer only to the general government.

In opening this discussion, Professor Osborn indicated two points upon which he expected me to speak. The one was the ultimate practical importance of pure scientific work from the standpoint of applied entomology, and the other was the preparation of men by our colleges and universities especially for State work. In regard to the first topic, the case is so self-evident as to require little elaboration. It is upon work in pure science that the entire superstruc-

ture of economic entomology has been built, and workers in applied science are constantly making use of the results of the labors of workers in pure science. The practical outcome, however, of the labors of the workers in pure science is indirect, while the practical outcome of those who work in the economic applications of science is direct. In any emergency the direct method is the one which is immediately productive of practical results. The study of economic entomology is a study of facts which will enable us to meet one great and widely extended emergency. It must be conducted by the direct method, and the reason why this country stands in advance of the rest of the world in this application of science is because we are a practical people and have adopted the direct method. There can be no doubt, however, that it is necessary for the most successful economic worker to have had a sound training in pure science.

This leads us naturally to the second point—the preparation of men by universities especially for State work. The first training should be, as just stated, a broad one in pure science, but the practical applications should follow with as rigid a course of instruction as can be given. University teachers should make a study of the markets for the brains and training of their students. They should study the conditions of those markets and their needs. This is self-evident. But where is there a college professor who has made a careful study of the practical scientific needs of the Government? Some years ago the President of Vassar College visited in Washington during the Easter vacation. He spent his days visiting the scientific branches of the Government service. He spent his evenings at the Cosmos Club talking with the heads of those bureaus. He went home and arranged a course of lectures on the scientific work of the Government to be delivered for the most part by the men actually at the head of these branches of work. His aim was simply one of broad education, and I doubt whether he had any practical point in mind for the future of his students beyond the acquisition of general knowledge, but you will readily see that this idea might be used in a most practical way.

Men in charge of university departments of scientific work should keep closely in touch with the Government work along similar lines. They should be encouraged to do this by the Government. Government should employ their services wherever they can be of use, and such cases are numerous. They themselves should be able, with the intimate knowledge acquired by official association or by close investigation of Government work, to lay out lines of study which will fit their students to take a hand in Government work. In many cases, of course, this cannot be thoroughly done in university laboratories at the present time. Very few college graduates can pass the special examinations for certain scientific positions under the Government without training which they have secured outside of the colleges. A study of such conditions will show just how this is to be done, and universities will find it to their advantage to increase their facilities for instruction in such directions, and certainly it will be to the advantage of the Government scientific work. This is by no means a new idea. Several practical college men have been asking this question of men in charge of Government bureaus and only recently the newly elected President of the Massachusetts Institute of Technology, who went there direct from a Government bureau, sent out a circular letter asking Government officials how he can best train men in Boston for other branches of Government scientific work than that of which he was in charge.

What does government do for zoology,

and what ought it to do? If it does not do as it ought, why does it not do so?

Aside from the meager sums which the State experiment stations supported by the Government allot to animal industry and to economic entomology, the zoological activities of this Government center at Washington. There are three institutions which do zoological work for the government. The Smithsonian Institution, with its National Museum and National Zoological Park branches, is the only one of the three which cares for pure zoological science. The U. S. Department of Agriculture, with its Bureau of Animal Industry, its Biological Survey, and its entomological service, is wholly economic in the aims of its zoological scientific work. The third of these institutions, the U. S. Commission of Fish and Fisheries, was also established by the Government for a purely economic purpose.

It is not my intention to dwell at any length upon the relative merits of economic and pure scientific work. I have a strong conviction that humanity gains far more from scientific work undertaken with an economic aim than from the labors of the other class of scientific men, and I believe it to be a most unfortunate condition of affairs that hundreds of the men, best fitted by brains and training to attack the many economic problems which are fairly crying for solution, are delving away in their search for truths and principles which when found have only a remote bearing, if any at all, upon the sum total of human happiness. I was once filled with the resounding majesty of the phrase 'science for science's sake,' but now, while I admit the grandeur of the idea, I have come to parallel it and its opposite in my mind with the contrast between abstract and practical Christianity—both beautiful, but one for gods and the other for men.

Now what is Government doing for these three scientific institutions at Washington?

The Smithsonian Institution receives each year $246,540, for the National Museum, and $75,000, for the National Zoological Park. The National Museum employs 33 scientific men, and the National Zoological Park, 2. All are pitifully underpaid. The amounts spent on purchase of collections have been extremely small. Neither the Museum nor the Park has a responsible head in the proper sense of the term. The Secretary of the Smithsonian Institution supervises the work of both branches and alone asks Congress for their appropriations. The personnel of the scientific force of the Museum is admirable in quality but absurdly insufficient in quantity. Not a scientific man on the force has the proper facilities for work. The collections are large but they are one-sided and there is little money to supply the deficiency. Underpaid, with few facilities, grievously dissatisfied with conditions, nothing but the rare enthusiasm which scientific work inspires keeps these able men at their labors. The National Museum needs a new building planned for all time to come. It needs now an annual appropriation of double the present size. As soon as the beginning of a new building is made it will need an appropriation of ten times its present size. Think of what the words *United States National Museum* should mean and then think how the present institution fits the name! Government has not given a proper amount of money and Government shows faint signs of ever giving it. Why? Because Congress has not been made to see the importance of the subject; because Congress has not been asked for the money with sufficient force and with sufficient argument. The Board of Regents of the Smithsonian Institution might make this request and back it with all the weight of the illustrious names of the men who compose that body. The Secretary of the Smithsonian Institution

might make this request and urge it strenuously and incessantly and with an ability which few other men possess. The scientific men of the country might urge it. Organizations of many different characters might petition Congress for it. But the men who best know the truth about the present conditions, the scientific employees of the National Museum, may say no word.

The National Zoological Park is naturally by no means as important an institution as the National Museum, since it is concerned with but one branch of science, but it falls as far short of what it should be as does the National Museum, and for the same reasons. Double the means and a force of zoologists are its important needs. This institution should naturally be a branch of the National Museum, but the National Museum as it should be and as it will be is too great a branch of Government to be controlled by the Smithsonian Institution. It should have its independent organization; it should have its responsible director who will spend his winter days laboring with Congress for appropriations and his nights planning broad lines of development. The Smithsonian Institution has done a great and good work, but it should not be given control of great national institutions like the ideal national museum. Infinitely better would it be were the Smithsonian Institution attached to the National Museum as one of its component parts. The Smithsonian has played its rôle with the Museum. It officiated at its birth and nursed it through its childhood; but the youth is now cramped. It must grow. It must burst the Smithsonian cage and stretch out its own appealing hands directly to Congress.

The U. S. Department of Agriculture is the first of the Government bureaus which does economic zoological work. Here as in the National Museum the men are underpaid, but the facilities for work are vastly better. Government appreciates more readily work which promises immediate economic results and hence money for such work is more easily gained. Scientific men in the Department of Agriculture refuse positions offered elsewhere at higher salaries, on account of these better facilities. Good research work and initiative in investigation are encouraged. Nothing could be more ideally perfect than the relation between the present head of the Department of Agriculture and his scientific corps. Four years ago he announced his policy in this regard in conversation with one of his scientific chiefs in the following words: "I am here to facilitate your work, not to dictate to you. Make your plans, conduct your investigations, and I will help you with all my strength, but I shall hold you responsible for results." Scientific men should honor James Wilson for the introduction of this novel principle in the administration of a Government scientific bureau. The good, sound, progressive scientific work now being done by his corps is everywhere commended, and I am proud to be connected with such an organization. New laboratory buildings are needed here, but there is no fear that they will not come in the immediate future.

The U. S. Commission of Fish and Fisheries deals with a single aspect of zoology and with a single industry. Just why scientific men are chosen as the administrative heads of the U. S. Geological Survey and the U. S. Coast and Geodetic Survey and not, since the days of Baird, for the Fish Commission is one of the mysteries of Government. Nearly four years ago this Society did the creditable thing in passing resolutions and sending them to Washington in the hands of Professor Osborn, protesting against the appointment of any other than a scientific man as the director of this important branch of applied scientific work. The present incumbent of the

office is a good official and no personal objections are to be raised against him. The principle, however, is not a good one, and the next appointee to this office should be a man who combines scientific attainments with administrative ability. The old popular idea of a scientific man—that he lacks what is called 'common sense,' that he is impractical—is an unfortunate estimate gained from unappreciative observation of workers in pure science, but it no longer holds. Henry, Agassiz, Baird—all men of affairs, now gone, did much to change this popular estimate, and the host of brilliant men who have succeeded them—men of high scientific rank, who control the destinies and shape the policies of great institutions, and who turn out work of great and important practical value, have demonstrated beyond the slightest doubt that scientific men are the broadest men of affairs, that they are practical men, and that they are fit to be leaders not only in thought but in action.

It is doubtful whether any government in existence does as much for the encouragement and development of science as does our own. This has repaid her a thousand fold, and the sound judgment of the American people and their patriotic pride in national attainment will effect a steady increase in governmental support of scientific work in spite of temporary checks. With scientific men, however, must come the initiative. They must point out the needs and the ways and means by which these needs must be supplied. This fact is the justification of this discussion.

L. O. Howard.
U. S. Department of Agriculture.

Is it not true that the attitude of the State toward science and scientific research is at all times greatly influenced by the shaping of public sentiment through the work of scientific men themselves? This is a practical age, and in America especially the tendency is more and more to give a practical trend to almost every line of research. We find, therefore, as a matter of fact, that there is a general lack of interest in, and support of, matters having to do with pure science alone, while on the other hand all questions having practical application, and even those in which the practical end is remote are received with commendable liberality. Taking the field of botany, for example, it would be difficult, if not impracticable, to secure support for the preparation and publication of purely floristic monographs, unless it could be pretty clearly shown that such a project had some practical end in view.

In so far, therefore, as the attitude of the State toward all work of this nature is concerned, there is a great deal of conservatism to be overcome, and this conservatism is especially pronounced where pure science is brought strongly to the front. The reason for this is not far to seek, for its roots lie imbedded in the selfishness of human nature, which, acting through organization in the shape of government, sees, or thinks it sees, in the aggressiveness of science a menace to existing institutions in some form or other. While science in its nature is aggressive, the men who do most to advance it often lack aggressiveness, and for this reason the far-reaching effect of science as an educational factor at the present time is not fully understood or appreciated.

This brings me more particularly to the main question I wish to raise in this discussion, namely, what should be the attitude of the scientific man toward the cause he represents. I am strongly of the opinion that he owes it to himself and to his work to put forth every legitimate effort to advance the interests of the cause. He should of course keep constantly before him the fact that to bring honor and credit to the

work he must recognize the duties of life which Professor Osborn has already pointed out. This will not allow him, however, to sit calmly down and wait for the material things of the world to come to him. The men who have it in their power to aid him are too busy to go out of their way to render help unless that help is sought. There exists a mistaken idea that because one is engaged in or may be directing scientific work he is the one to be sought. We see this idea shaping the policy followed in some of our important institutions, as already pointed out by Dr. Howard, and as a result they are being outstripped in every way by others which have a better appreciation of what is necessary to influence public sentiment. After all, the public and those who represent the public look at this matter in its true light, for they have been educated to expect those who are responsible for important lines of work to make their needs plainly understood.

With the distinctly utilitarian sentiment toward science, as pointed out, the question arises as to what stand should be taken by those charged with the guidance of the work with respect to shaping a general policy which will meet the demand for practical ends, and at the same time advance the cause of science to the fullest extent. Extremes must be avoided, for if the tendency is too strong toward pure science, opportunities will be lost through lack of support, and if toward ultra-utilitarianism, science itself will be endangered through the development of false views, erroneous statements and lack of judgment—rocks and reefs that must by all means be avoided. There is always a medium ground, however, where science and practice can each be made to help the other and each be the stronger for the support thus gained. This is the stand, I may say, that is now taken by those charged with most of the work conducted under the auspices of the Government, and which, during the past fifteen years at least, has resulted in a rapid development of all work along broad and safe lines. Most of the departments of the Government, wherein scientific work is carried on, owe their existence to a demand for greater knowledge on problems concerning the interests and welfare of the people. In the early days of this work too much attention was given to a mere diffusion of knowledge without regard to its source, and as a result of this original research did not receive the attention it deserved. In later years, however, the importance of research is becoming more and more appreciated, and as a result the work has increased in strength and now commands the respect it deserves. It is unnecessary to dwell upon any specific work now being done by the Government, as the object of this discussion, as I understand it, is more to deal with general matters, and certain of the details have already been given by Dr. Howard. I will conclude what I have to say with just one statement, namely, that the future attitude of the State toward scientific research will in large measure depend on our own efforts individually and collectively. Let us therefore go forth with a determination to advance the cause of science in every way and to stand firmly for the great principles of truth it represents.

B. T. Galloway.
U. S. Department of Agriculture.

In considering the attitude of the State toward scientific investigation it may be well to remember that with us the State is the people, ours being a government of the people, by the people, for the people. What then is and what should be the attitude of the people toward scientific investigation? Probably very much the same as their attitude toward education, and concerning this there can be no question. From the very beginning our people made careful provision for education by the establishment of public

schools. They have asked, and answered emphatically in the affirmative, the question: Does education pay; and I believe that they are asking and answering the other question, Does scientific investigation pay, very much in the same fashion. The golden stream of benefactions which has now for many years been flowing in upon educational establishments proves that the people firmly believe that education pays. They believe in education.

I have been very much interested to hear the quotation from the 'Message of Washington' urging upon our people the importance of promoting scientific investigation and research. I believe that the American people are, in increasing numbers, large-minded enough to look through and beyond the nearer every-day phenomena and to realize that the promotion of discovery, no less than the promotion of learning, pays in every sense of the word. They perceive that it pays in the highest sense, in the enrichment of intellect and the cultivation of faculty. They perceive also that it pays in the utilitarian sense, in that it gives leadership among the nations of the earth in the applications of science which always follow hard upon the heels of discovery. Professor Osborn has done well to point out that those nations which support research most liberally are those which are taking the lead in the industrial world to-day.

I remember a saying of General Walker's, that he firmly believed that we should outgrow the necessity of protection, and we are beginning to-day to witness the fulfilment of his prediction. The enormous development of our export trade, based upon our scientific and economic system of manufactures, arts and industries, marks that over-growth of the merely home market and local protection which General Walker was far-sighted enough to foresee. I believe that, if once the people realize what a burden and a hindrance is inflicted upon scientific research, and thereby upon educational and industrial progress, by the tariff upon microscopes, dissecting instruments, models, diagrams and other apparatus of research and instruction, that tariff will melt away like dew before the sun.

And so it is also, I believe, with the relations between pure and applied science. The barrier between them is fading away, because they are constantly drawing nearer together and over-growing one another. Pure science has given to applied science the fundamental elements of truth, perfection, knowledge and skill. Applied science, on the other hand, has developed so prodigiously as to react favorably upon pure science, furnishing for it rich sustenance and fertile soil in which it may flourish. An hour might well be spent in pointing out not only the aid which pure science has given to applied science, but reciprocally the enormous development of pure science and scientific investigation wrought by applied science. It is one of the marvels of the day that many highly organized and differentiated industries, and even many of the coarser arts, find their narrow but sufficient basis of profit in the employment of the results of latest and most advanced researches in pure science.

Our age has been called by one of the speakers who has preceded me, a practical age, and so it is; but it is an age which has discovered in science the Promethean fire. The highest and truest utilitarianism of to-day is a generous cultivation of scientific investigation, not indeed for its own sake, but for the sake of the results which are sure to follow from it. As to the pursuit of science for its own sake, Professor Osborn has, it seems to me, used a happy illustration in referring to the scientific investigations of the Government as an investment rather than an immediate outlay for current expenses. As to pure science pursued strictly for its own sake, I think we may

rather describe it as an investment from which we still expect ultimately some return. Science for its own sake is, after all, much like investment for its own sake; which has never been made, I fancy, even by the least practical of philanthropists.

For illustration of public appreciation of scientific research as a necessity for practical results, I may give an example. When in 1886 the newly organized State Board of Health of Massachusetts attacked scientifically the problem of protection of the purity of inland waters, they reported to the people of that State that in order to do the work required by the Legislature it would be necessary to inaugurate and prosecute special and novel investigations, and for this and other purposes they asked for an appropriation of $30,000. This sum was immediately and cheerfully granted by the people for this purpose and has ever since been continued, annually, with the result that the Massachusetts experiments are referred to with commendation and advantage by bacteriologists and engineers all over the world. Again, when it became clear that antitoxin for diphtheria had become a public necessity and its proper preparation a public duty, the same State Board of Health secured the services of one of the most distinguished bacteriologists in the country, Professor Theobald Smith, and requested him not only to prepare antitoxin for the citizens of the State, but also to investigate the best methods of its preparation and preservation, besides other cognate and novel but pressing problems in the field of pure science. Here also the most thorough-going utilitarianism has proved to be scientific investigation pushed to its utmost limits.

Just here also the State, by and for the people, might well do much more than is yet done. As a nation we have hitherto played but an insignificant part in those scientific inquiries which underlie the medical and sanitary arts. As a nation we cannot claim any of the credit for originating the germ theory, or antiseptic surgery, or for laying the foundations of modern bacteriology, or for the discovery of antitoxins or for elucidating the ætiology of malaria, or for inventing the agglutination test for typhoid fever. We may be excused for our inertness previous to 1870, because until then the civil war or its sequelæ claimed all our energies; but from comparative inactivity in these matters since that time—excepting in one honorable division of the government service, the agricultural,—we have no good excuse to offer. If we are to hold our proper place among the nations in the prosecution of medical and sanitary inquiry the State or the States must lend their powerful aid, or else private enterprise or the universities must do far more than they have yet done in this direction.

In this connection, and especially on this platform, it will not be out of place for me to refer to the intense satisfaction which all lovers of good government and of the intelligent and scientific administration of public affairs feel, that Dr. Gilman, the founder of purely university education in America, and the president of this University, which has done so much for the cause of scientific investigation, has consented to accept the presidency of the National Civil Service Reform Association; for I believe that the introduction of more science and more scientific investigation into the civil service means the development and extension of a rational system of government based upon merit, rather than partisanship or spoils. Here Harvey, the father of physiology, raised the true standard for us when he exclaimed: 'I avow myself the partisan of truth alone.'

I cannot close without expressing my cordial assent to another point made by Professor Osborn and my belief in its extreme importance, viz., the reciprocal duty which the scientific worker owes to the State.

Who can forget the famous and stinging characterization of that tutor in Magdalen College whom Gibbon's caustic pen has embalmed in eternal disgrace, one Dr. ———, of whom Gibbon said, 'he well remembered that he had a salary to receive, and he only forgot that he had a duty to perform.' I have always been sorry that Dr. ——— was a teacher and glad that he was not a scientific man. President Hadley, I think, struck the right note when he cautioned young men not to ask themselves 'How much can we get out of college?' but rather, 'How much of ourselves can we put into it?' Science, like religion, demands of her votaries lofty sacrifices and personal devotion, and if they are public servants their debt to her is always not less but more.

WM. T. SEDGWICK.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

THE ALBANY MEETING OF THE GEOLOGICAL SOCIETY OF AMERICA.

I.

THE thirteenth annual meeting of the Geological Society of America was held in Albany on December 27, 28 and 29, 1900. The fellows were called to order by the retiring President, Dr. George M. Dawson, Director of the Geological Survey of Canada, at 10 A.M. on Thursday, in the chapel of the Albany Academy. A very gratifying number of members was present and during the sessions from 50 to 60 were in attendance. All felt the significance of meeting in the city where stratigraphical geology received its greatest single impetus in America and where the classification of most of the Paleozoic was chiefly worked out. Memories of James Hall were in all minds and frequent reference was made to the late venerable State Geologist, first President of the Society.

At the opening meeting brief addresses of welcome were made by Dr. F. J. H. Merrill, State Geologist, and by Dr. J. M. Clarke, State Paleontologist. The Council then presented its written report, which showed the Society to be in a very flourishing condition. During the year one fellow, Mr. Franklin Platt, has died. The present enrolment is 248, and the financial condition is gratifying. The following officers were declared elected:

President, Charles D. Walcott, Washington, D. C.; *First Vice-President*, N. H. Winchell, Minneapolis, Minn.; *Second Vice-President*, S. F. Emmons, Washington, D. C.; *Secretary*, H. L. Fairchild, Rochester, N. Y.; *Treasurer*, I. C. White, Morgantown, W. Va.; *Editor*, J. Stanley Brown, Washington, D. C.; *Librarian*, H. P. Cushing, Cleveland, O.; *Councillors:* Samuel Calvin, Iowa City, Ia.; A. P. Coleman, Toronto, Can.

A memorial of Franklin Platt, prepared by Persifor Frazer was then read by W. M. Davis, and at its conclusion the reading of scientific papers was immediately taken up.

Experimental Work on the Flow of Rocks recently carried out at the MacGill University, Montreal: FRANK D. ADAMS.

This paper gave the results of an investigation in which the effects of very heavy pressure on rocks were studied with a view to ascertaining how the gigantic movements which geologists observe in the strata of the earth's crust have taken place.

Marble was the rock on which most of the work was carried out, but harder rocks such as granite are now being studied as well. Small columns of marble an inch in diameter and an inch and one-half high were carefully turned, polished and then very accurately fitted into heavy wrought iron tubes constructed on the plan of heavy ordnance, by wrapping strips of wrought iron around a core of soft iron and welding the whole together. The core of iron was then bored out and the marble substituted for it. Heavy steel pistons were fitted into each end of the tube, and the rock was thus submitted to very high pressures, often for several months continuously, in espe-

cially constructed machines capable of developing pressures reaching nearly 100 tons to the square inch.

Under high pressures the marble was found to flow, bulging out the iron tube that enclosed it on all sides. When the iron tube was cut away a solid block of marble was obtained, which had completely altered its shape. It was found, however, that the marble in these cases was only about half as strong as the original rock.

Other columns of marble were then heated to temperatures of 300 C. and 400 C. and while thus heated the pressure was applied as before. Under these conditions the rock was found to flow readily and to retain its strength much better, being nearly as strong as the original rock.

In the third series of experiments the marble was not only heated to the temperatures before mentioned, but at the same time water under a pressure of 460 pounds to the square inch was forced through it while it was being compressed. Under these conditions, the marble after being molded was found to be as strong as it was originally.

A microscopical study of the structure of the deformed marble shows that in these two latter cases the crystalline grains composing the marble had glided on one another.

This structure is exactly the same as that which is produced in a billet of iron when it is heated and then hammered or rolled, or in a button of gold when flattened in a vise, so that the marble *flows* just as any metal does when submitted to pressure, except that under the ordinary conditions at the surface of the earth the brittleness of the marble causes it to break before the flow point is reached. In the depths of the earth, however, being hemmed in by other rocks, it flows as in the experiments.

The paper was elaborately illustrated by specimens and by many lantern slides, showing the machines employed, as well as the marble before and after compression. They also illustrated its structure as compared with that of various rocks found in the earth's crust and with hammered iron.

In discussion B. K. Emerson asked (1) whether the cylinders of marble contained any water before they were put into the machine; (2) if any schistosity resulted, and, if so, in what way it was related to the optical properties of the calcite grains; (3) if the marble rebounded on the release of pressure.

J. E. Wolff inquired whether the water that was forced in passed around or through the cylinder of stone, and if solution played any part.

G. K. Gilbert asked if the speaker could draw a parallel between the pressures employed and the depths within the earth corresponding to them.

In reply Professor Adams stated (1) that the cylinders of marble were kept in a perfectly dry laboratory, and that while no determinations of their content of water had been made, they were practically dry when put in the machine; (2) he had noted no rebound. The marble was first compressed and then accommodated itself to the pressure by flowage; (3) he had been unable to note any effects of solution as a result of the entrance of the water. The results were the same with or without the water, except that with the water the resulting disk was stronger. The water entered at the top under 460 pounds' pressure to the square inch and emerged at the bottom. The water had dissolved a little copper from the tube of entry, which was precipitated on the bottom of the marble. He could not state positively whether it went through or around, but the marble was in a bath of vapor.

J. E. Wolff suggested that waters with some dissolved dye or easily reducible salt be employed so that the last point could be

determined, and that ordinary limestone be compressed to see if it would yield marble, and that impure varieties be also used so as if possible to produce the silicates familiar as a result of metamorphism. G. K. Gilbert estimated approximately the depth which corresponded to the pressures employed. Roughly one vertical foot of rock corresponds to an increase of one pound per square inch, or one-half ton per 1,000 feet. Forty tons would therefore correspond to 80,000 feet or about 16 miles. This should be reduced somewhat, as rock is slightly heavier than the assumption, but the difference is slight.

C. D. Walcott remarked the deformation which he had observed in the rocks of the ranges in California and western Nevada, and emphasized the different behavior of brittle rocks and tough rocks, illustrating his remarks by photographs. The brittle rocks break while the tough rocks flow—the former being often driven into the latter. He suggested that Dr. Adams experiment with cylinders of varied tenacity.

G. K. Gilbert raised the point that rocks may compress slightly while they are within the elastic limit, *i. e.*, before they yield, flow or otherwise deform. He suggested the importance of determining the amount of this.

B. K. Emerson remarked the importance of allowing for the phenomena of recrystallization in interpreting the results.

Dr. Adams then thanked his colleagues for the suggestions, and stated his intention of carrying them into effect as far as possible.

The paper was felt by all to be one of the most important ever presented to the Society, and the investigations are of such significance that further results will be eagerly looked for.

Geomorphogeny of the Klamath Mountains: J. S. DILLER, Washington, D. C.

During the Neocene the Klamath mountain region of northwestern California and southwestern Oregon, by long-continued erosion, was reduced to a peneplain and the resulting marine sediments, rich in fossils and deposited along the ocean border, recorded its age. The Neocene strata were compressed and tilted, and with the Klamath peneplain and monadnocks were uplifted somewhat differentially several hundred feet above its former level. The invigorated streams in the rather long succeeding epoch of stability cut wide valleys across the peneplain to the coast, where extensive wave-cut terraces were developed. A much greater differential uplift followed, and elevated the region to an altitude of 1,200 feet to 2,000 feet, for the Klamath peneplain near the coast of 7,000 feet, and near the crest of the range causing the streams to cut deep canyons before the close of the glacial period. Near the northern border of the Klamath Mountains on the coast there has been a recent subsidence converting the lower courses of the rivers to tidal inlets.

M. R. Campbell inquired if the peneplain topography could be traced all around the mountains. The speaker replied that, while it was not everywhere present, it could often be recognized. Mr. Campbell then remarked the interesting parallelism with the Appalachians, the similar shading of plains into each other and the similar interpretation of escarpments.

As Mr. Diller had referred to great numbers of small lakes upon the elevated plain and with local 'fluviatile' rather than 'lacustrine' sedimentation, W. M. Davis suggested for the phenomena Penck's term of 'continental' sedimentation. He compared the region to the central plateau of France, and urged that under compression surface plains would warp in a general way like single strata, so that in a principal ascent of a large order there would be alternate ascents and descents of a smaller order of magnitude.

President Dawson referred to the Eocene peneplain of British Columbia that was protected from the sea during its formation by an intervening range of mountains, and was therefore subaërial in its character. He asked why the Klamath peneplain might not be explained by marine denudation. Mr. Miller replied that in the Klamath case Eocene strata were themselves trenched, and, therefore, the leveling was later; and that the entire absence of marine sediments compelled him to infer sub-aërial agencies. G. O. Smith spoke of the peneplain of Washington that lies between the Klamath mountains and British Columbia. It is post-Miocene, as it cuts Miocene strata, which have themselves been deformed, probably in the case of basalt by slipping along multitudes of joints, as suggested by Bailey Willis. G. K. Gilbert described the great Alaska peneplain, which slopes upward and eastward from the Alexander Archipelago to heights of 5,000 feet and more in the mountains. It has been vividly brought out by the photographs of the Survey of the International Boundary. He also remarked the parallelism that existed between the Pacific and Atlantic physiography. President Dawson cited mountains of the Pacific coast 7,000 feet high that have been sculptured out of uplifted plains. He sounded a note of caution, however, lest the observer be misled into believing in peneplains which had no real existence. Above a certain level degradation is abnormally active and rapid, and from this alone mountains may reach a common and deceptive level and yet not be stumps of peneplains. Mr. Gilbert, however, replied that his Alaska mountains were shouldered and therefore not open to doubt.

Origin and Structure of the Basin Ranges: J. E. Spurr, Washington, D. C.

The structure of most of the ranges which have been hitherto studied in the Great Basin region was first examined in detail, and in each case deductions were made as to the relative importance of erosion and of direct deformation, by either fault or folds, in determining the present topographic relief. Finally a general statement as to the origin of this relief is arrived at. The history of erosion in the region, and that of deformation, so far as these are known, were discussed separately; and the history and foundation of the fault hypothesis as applied to these ranges were examined. The conclusion arrived at is that the ranges in general owe their existence to the long-continued erosion of rocks folded and faulted by many successive movements, and that it is only exceptional that the folds or faults are expressed in direct deformation of the present surface.

This paper was read in abstract by C. D. Walcott and was illustrated by cross-sections. It involved a great amount of detail, however, which it is not possible to summarize, but which will be extremely valuable as a matter of record. At its conclusion the morning session adjourned. On reassembling the first paper read was the following:

The Tuff Cone at Diamond Head: C. H. Hitchcock, Hanover, N. H.

This cone is one of the famous ones of the Hawaiian Islands, and is interesting and exceptional in that coral, limestone and marine shells are copiously mingled with the tuffs, giving rise to a difference of opinion as to whether the cone is submarine and therefore marks a notable subsequent elevation of the land, or whether the organic remains have been ejected to their present positions along with the tuffs. No discussion followed, as the Fellows seemed too unfamiliar with the locality to hazard an opinion.

An Hypothesis to account for the Extra-Glacial, Abandoned Valleys of the Ohio Basin: Marius R. Campbell, Washington, D. C.

The lower courses of the Allegheny, Monongahela, Kanawha, Guyandot, Big Sandy and Kentucky rivers are characterized by abandoned channels which generally range from 100 to 200 feet above the present streams. Generally these channels are deeply covered with silt, but sometimes the rock floor is only partially obscured by a thin layer of sand and gravel. The streams which have forsaken these valleys have sought new routes, along which they have carved deep channels through the upland topography. Teays Valley in West Virginia is perhaps the most noted example, but the old channels at Carmichael and Masontown on the Monongahela River and at Parker on the Allegheny River are also well known.

No reason has been assigned for the abandonment of these channels; they can not be considered as 'ox-bows,' and they are all beyond the limit of glacial ice. The present hypothesis seeks to explain them through the breaking up of river ice and the formation of local ice dams, which were of sufficient height to force the water over the lowest divide in the rim of the basin and which persisted long enough for the stream to intrench itself in its new position.

The paper was illustrated by many lantern slides of topographical maps. It brought on an extended discussion, because the Fellows were generally familiar with the subject, since for many years Teays Valley has not been omitted at a meeting, but has come up in one connection or another, and has grown to be a sort of geological Banquo's ghost, that will not down. I. C. White opposed the ice jams and argued in favor of one large dam produced by the continental glacier when it crossed the Ohio river. He emphasized the softness of the rocks at the headwaters of the southern tributaries and the harder ones further down. W. M. Davis suggested lakes as a possible obstruction which had developed cut-offs by gradually falling waters. G. K. Gilbert opposed the explanation by means of a glacial dam, and suggested a possible change in climate, with increasing cold and a filling of the valleys with ice, which brought about a rearrangement of the drainage. M. R. Campbell opposed the explanation by lakes and by a glacial dam, because of the lack of uniformity in the sedimentation which should appear with such an extended cause. A. P. Brigham called attention to the fact that the new courses assumed by some of the rivers were longer than the old and raised the point that ice jams ought to cut off and shorten meanders. M. R. Campbell admitted the slightly longer courses in a few cases, but still supported the ice jam as against all the other causes suggested.

The Alleged Parker Channel: EDWARD H. WILLIAMS, Jr., Bethlehem, Pa.

The paper was a brief one, which described one of the cases cited by Mr. Campbell, located at Parker, Pa. Instead of an old channel, the apparently abandoned detour of the Allegheny river was explained by the disappearance or effacement of the divide between the headwaters of two tributary streams.

This general subject having been so well gone over, the above paper was not specially discussed.

Apparent Unconformities during Periods of Continuous Sedimentation: GEORGE B. SHATTUCK, Baltimore, Md.

The paper was based on certain phenomena which the author had observed along the shores of Chesapeake Bay. Lenticular beds of black clay were found resting with apparent unconformity on older sediments and provided with cypress knees and other fossilized vegetation. The explanation advanced was that minor stream valleys had been ponded during subsidence of the shore by bars formed across their mouths. Thus, while the sea crept inland and formed extended sediments, these ponded embay-

ments would be the place for the gathering of clays and vegetation which would lie unconformably with the synchronous shore deposits. The paper was very clearly presented and was suitably illustrated by the lantern.

Origin and Age of an Adirondack Augite Syenite: H. P. CUSHING, Cleveland, Ohio.

Recent work in the field, together with chemical analyses, demonstrates that the Adirondack anorthosite shows a certain amount of differentiation and passes locally into an augite syenite, all intermediate phases being found, as was contended by the writer in a paper read before the Society two years ago. There is, however, much evidence now at hand to show that much of the great body of augite syenite gneiss in the Adirondacks is older and to be referred in age to the main body of gneiss of the region, whatever that may be. Criteria for distinguishing between the two syenites have not been developed. The paper was presented by permission of the State Geologist, and was illustrated by an extensive series of analyses. J. F. Kemp remarked the abundance of related rocks in the regions to the south, and then the session adjourned for the day.

In the evening the annual dinner was held, with Professor Emerson in the chair and fifty-five present. An address of welcome to the Society was made on behalf of the Regents of the University by Dr. T. Guilford Smith. The proposition for the erection of a State museum in which to house the collections of the various scientific departments was discussed, and resulted in a subsequent resolution which will be given below.

On Friday morning the Society met at 9:30 and listened to a report of the Committee on Photographs by its chairman, N. H. Darton. The collection now numbers over 2,000, and is stored in the building of the U. S. Geological Survey in Washington. It is a valuable one, and will be revised and condensed, and a published list will be prepared at an early date. This collection has made accessible to the Fellows many photographs made by surveys, both State and national, and by private individuals.

The Laurentian Limestones of Baffinland: ROBERT BELL, Ottawa, Canada.

The discovery of great quantities of crystalline limestones in Baffinland was announced in the writer's 'Summary Report for 1897.' The geographical position and physical aspect of the region were described. The general character of the Laurentian System in Hudson Straits was outlined. The rocks of the north side are newer or Upper Laurentian, as far as known, and differ from those of the south shore. Regularity of strike and dip is pronounced. Enormous developments of crystalline limestones have been met in southern Baffinland. Their general characters were described. Great thickness is presented by the beds, some of them being over a mile across and running regularly for long distances. They are evidently stratified aqueous deposits. Questions were raised as to the origin of such limestones. The associated rocks are gneisses and schists, and the accompanying minerals are chiefly feldspar. Owing to the absence of trees, the limestones are conspicuous in the landscape and are not more eroded than the gneisses. Comparisons were drawn with Laurentian limestones elsewhere, the former physical conditions and the older and newer glaciations of Baffinland were discussed as affecting the limestones. The existing glaciers there were described. The paper was illustrated by the lantern. There was no discussion.

JAMES F. KEMP.

(*To be concluded.*)

THE AMERICAN PHYSICAL SOCIETY.

THE American Physical Society held its annual meeting at Columbia University on Thursday, December 27, 1900. The following officers were elected for the year 1901: President, H. A. Rowland; Vice-President, A. A. Michelson; Secretary, Ernest Merritt; Treasurer, W. Hallock; Councillors, Henry Crew and E. B. Rosa.

Professor M. I. Pupin, in a paper on anomalous propagation of electrical waves, called attention to certain peculiar results which he had obtained when trying to improve the telephone transmission of a line, by counteracting its capacity by the introduction of self-induction coils between the outgoing line and the return. By this means he was able to considerably improve the transmission of certain frequencies, but he had not succeeded in reenforcing a sufficient range of frequencies to avoid a serious distortion of the quality of articulate speech.

The discussion by Professors Rowland and Webster and others raised the question as to whether Professor Pupin's abnormal velocity of transmission, considerably above that of light, derived from the relation that velocity is equal to the wave-length divided by the period, is justifiable, since it is doubtful what is to be called the 'wave-length' in a coil.

President Rowland reported that his search for an electromotive force due to dragging a wire through the ether had so far failed, and that it would appear that so far as the limits which he had used were concerned, it was safe to conclude that no positive results are attainable.

In a theoretical consideration of certain magneto-optical phenomena President Rowland pointed out that by considering each of two particles as having quantitatively different charges of electricity, he had been able to deduce formulæ which account for many of the electro-optical effects, as the Zeeman, Faraday and other effects, as well as refraction, double refraction, dispersion, dispersion in double refraction and absorption. If the charge of one of the particles is practically infinite as compared with the other, then his formulæ reduce to the ordinary ones. If the two charges are equal, no Zeeman effect could take place.

Professor E. F. Nichols presented the results of his investigations upon the energy radiated from certain stars and planets as measured with his radiometer, which proves to be about thirty times as sensitive as the radiomicrometer of Professor Boys. The unit used to express the quantity of energy was the hundred-millionth part of the energy received from a candle at a distance of one meter, *i. e.*, 10^{-8} meter-candle. The results obtained were as follows:—Vega, 0.51, —Arcturus, 1.14,—Jupiter, 2.38,—and Saturn, 0.37.

Two papers by Professor R. W. Wood were read by the Secretary. In the first he outlined the method of making very efficient cyanine prisms and of showing their anomalous dispersion. In the second he called attention to certain peculiarities in the propagation of waves reflected in a spherical mirror.

A brief *résumé* of the work of the Paris Congress of Physics was given by Professor A. W. Webster. The reports of the congress have appeared in three volumes, and a 'Proces Verbaux.' It is of general interest that this congress by its commission on units expressed the belief that it is desirable:

1. That a unit of pressure be used, called the *bary*, which is the C.G.S. unit (that is a dyne per square centimeter). The *megabary*, equal to 10^6 C.G.S. units, may, for practical purposes, be considered equal to the pressure of a column of mercury 75 cm. high at 0°.C. under normal conditions of gravity.

2. That the *final* results of calorimetric experiments be expressed in the C.G.S. mechanical units (erg and joule).

3. That in the logarithmic subdivision of the spectrum the sections be called 'regions.' The visible region to include the part between 0.4 μ and 0.8 μ and bear the index 0, the infra-red regions having positive, and the ultra-violet, negative indices (thus, R_2 from 3.2 μ to 1.6 μ, R_1 from 1.6 μ to 0.8 μ, R_0 from 0.8 μ to 0.4 μ, R_{-1} from 0.4 μ to 0.2 μ, etc.).

4. It is desirable to reserve the word *density* to designate the quotient of mass by volume.

The titles of the papers read were as follows:

'On anomalous propagation of electric waves,' by M. I. Pupin.

'A search after a new source of electromotive force,' by H. A. Rowland.

'The theory of certain magneto-optical phenomena,' by H. A. Rowland.

'On the heat of Arcturus, Vega, Jupiter and Saturn,' by E. F. Nichols.

'On cyanine prisms and a new method of exhibiting anomalous dispersion,' by R. W. Wood.

'On the propagation of cusped waves and their relation to the primary and secondary focal lines,' by R. W. Wood.

WILLIAM HALLOCK.

AMERICAN MATHEMATICAL SOCIETY.

THE American Mathematical Society held its seventh annual meeting at Columbia University, New York City, on Friday, December 28, 1900. About forty persons, including thirty-three members of the Society, were in attendance during the two sessions. Vice-President Thomas S. Fiske occupied the chair. A special feature of the meeting was the election of officers and other members of the Council. Under recent amendment of the Constitution, taking effect at this meeting, the president of the Society is elected for a term of two years and is ineligible for immediate reelection. The number of members of the Council elected annually is increased from three to four. This provision with the recent inclusion of ex-presidents as permanent members brings the present membership of the Council up to twenty-four. The newly elected officers are: President, Eliakim Hastings Moore; Vice-Presidents, Thomas S. Fiske and Henry S. White; Secretary, F. N. Cole; Treasurer, W. S. Dennett; Librarian, Pomeroy Ladue; Committee of Publication, F. N. Cole, Alexander Ziwet, Frank Morley; Members of the Council to serve for three years, E. W. Brown, H. B. Fine, T. F. Holgate, W. F. Osgood; Member of the Council to serve for two years, E. W. Hyde.

During the six years since its reorganization as a national body, the history of the Society has been one of constant and rapid development. The membership has grown from 244 in 1894 to 357 at present. In 1894 the number of papers read at the meetings was 24; in 1900 it was 115. Since 1894 summer meetings have been regularly held, supplemented on two occasions by colloquia or special courses of lectures. These have done much to bring the members together and to create a more general interest. The rapid expansion of the Society led in 1898 to the formation of the Chicago Section, which fosters the interest of the Society in the West. By the founding of the *Transactions*, which has just completed a very successful first year, improved facilities have been provided for the publication of important papers read before the Society. A gratifying recognition of the Society's usefulness and efficiency is found in the liberal financial cooperation of ten leading universities in the publication of the *Transactions*. The *Bulletin*, which was founded in 1891 as a historical and critical review, has been greatly enlarged, although confining itself more strictly than before to its special field.

The administration of the business of the Society has been wisely left from the beginning in the hands of the Council, the time of the meetings being thus economized for the purely scientific proceedings. The

finances of the Society are in a satisfactory condition, a moderate reserve fund having been slowly accumulated. The Society also possesses a considerable library, as yet of unbound journals and works. It is hoped that arrangment can soon be made for binding the books and making them accessible to the members.

At the annual meeting the following twenty-five persons were admitted as members of the Society.

Dr. G. N. Bauer, University of Minnesota; Dr. J. R. Benton, Princeton University; Dr. H. F. Blichfeldt, Leland Stanford University; Dr. G. A. Bliss, University of Minnesota; Professor Joseph Bowden, Adelphi College, Brooklyn, N. Y.; Professor D. F. Campbell, Armour Institute, Chicago, Ill.; Dr. J. E. Clarke, Gilbert School, Winsted, Conn.; Dr. Euplio Conoscente, New York, N. Y.; Mr. Arthur Crathorne, University of Wisconsin; Mr. H. W. Curjel, Birkdale, Eng.; Professor L. M. Defoe, University of Missouri; Mr. B. S. Easton, University of Pennsylvania; Dr. L. P. Eisenhart, Princeton University; Mr. U. S. Hanna, University of Indiana; Mr. L. I. Hewes, Yale University; Mr. A. M. Kenyon, Purdue University; Professor C. N. Little, Leland Stanford University; Mr. E. L. Milne, University of Illinois; Mr. H. B. Mitchell, Columbia University; Dr. Asutosh Mukhopâdyây, Calcutta, India; Mr. W. S. Nichols, New York, N. Y.; Professor J. M. Page, University of Virginia; Dr. T. H. Taliaferro, Pennsylvania State College; Miss R. H. Vivian, University of Pennsylvania; Dr. N. R. Wilson, Royal Military Academy, Kingston, Canada. Six applications for membership were received. The Annual Register of the Society, containing a complete list of members, the constitution and by-laws, reports of the secretary, treasurer and librarian, etc., is now in press.

The following papers were read at the annual meeting:

(1) Dr. VIRGIL SNYDER: 'On some plane curves having factorable parallels.'

(2) Professor E. D. ROE: 'On a formula of interpolation.'

(3) Mr. W. B. FORD: 'Dini's method of showing the convergence of Fourier's series and of other allied developments.'

(4) Dr. EMORY MCCLINTOCK: 'A simplified solution of the cubic.'

(5) Professor W. F. OSGOOD: 'On the minimum property of an external that meets its envelope.'

(6) Mr. C. J. KEYSER: 'Theorems concerning positive definition of finite assemblage and infinite assemblage.'

(7) Professor M. I. PUPIN: 'Wave propagation over bridged wave conductors.'

(8) Professor MORLEY: 'On a point in Sylvester's theory of canonical forms.'

(9) Professor HARRIS HANCOCK: 'On primary prime functions in several variables and a generalization of an important theorem of Dedekind's.'

(10) Dr. J. I. HUTCHINSON: 'On some birational transformations of a Kummer surface into itself.'

(11) Miss R. G. WOOD: 'The collineations of space which transform a non-degenerate quadric surface into itself.'

(12) Professor H. E. SLAUGHT: 'The complete form system of invariants of the group of 120 quadratic Cremona transformations of the plane.'

(13) Dr. JAMES MACLAY: 'Some geometrical theorems connective with a class of differential equations derived from Poisson's equation

$$\frac{\partial^2 z}{\partial t^2}=a^2\left(\frac{\partial^2 z}{\partial x^2}-\frac{mz}{x^2}\right).'$$

(14) Mr. J. K. WHITTEMORE: 'A note on cones of the second degree osculating developable surfaces.'

(15) Professor E. O. LOVETT: 'The types of line-sphere transformation.'

(16) Professor E. O. LOVETT: 'Note on differential geometry of n-dimensional space.'

(17) Dr. L. P. EISENHART: 'A demonstration of impossibility of a triply asymptotic system of surfaces.'

(18) Professor MAXIME BÔCHER: 'Some cases in which the identical vanishing of the Wronskian is a sufficient condition for linear dependence.'

After the meeting many of the members dined and spent the evening together.

The Chicago Section of the Society held its usual winter meeting at the University of Chicago on December 27th-28th. A report of the sectional meeting will appear later in this JOURNAL.

The next meeting of the Society will be held in New York on Saturday, February 23d. The Chicago Section will meet on

Saturday, April 6th. The summer meeting of the Society will be held at Cornell University, beginning on Monday, August 19th. Arrangements are being made for a colloquium in connection with the summer meeting. The committee in charge is now able to announce that Professor E. W. Brown will give a course of six lectures on 'The modern methods of dealing with the problems of dynamics and especially those of celestial mechanics,' consisting mainly of the work of Poincaré in this direction. A second course of lectures will also be arranged.

F. N. COLE,
Secretary.

THE AMERICAN CHEMICAL SOCIETY.

THE first session of the twenty-second general meeting of the American Chemical Society was held in Lewis Institute, Chicago, Ill., on Thursday, December 27, 1900. The session was called to order by President McMurtrie, in the chemical lecture-room of the Institute at 10.15 A.M. Dr. W. R. Smith, chairman of the Chicago section of the Society, was introduced and welcomed the chemists on behalf of the local section. He was followed by Howard S. Taylor, Esq., prosecuting attorney for the city of Chicago, who addressed a few words of welcome on behalf of the city and its citizens. President McMurtrie responded briefly on behalf of the Society, thanking the speakers for the cordial words of welcome.

After a few announcements a paper on 'Correction in the Determination of Urea by the Liebig Method,' was read by J. H. Long. This was followed by another paper by the same author, on 'Preliminary Note on the Optical Rotation of Certain Tartrates in Glycerol.' The latter paper was discussed by Messrs. W. A. Noyes and Long. A paper on 'The Decomposition of Sodium Nitrate by Sulphuric Acid, Part Two,' by C. W. Volney, was read by the author. Edward Gudeman presented a brief paper on arsenical poisoning, which was discussed by Messrs. Springer, Volney and Gudeman, and Miss Fossler. Two papers by C. L. Parsons, entitled 'A Simple Test for distinguishing Oleomargarine from Butter,' and 'The Use of Metallic Sodium in Blow-pipe Analysis,' were read by the Secretary in the absence of the author.

A photograph of the assembled chemists was taken, and, after a few announcements, the morning session was adjourned At the close of the session luncheon was served in the building, through the courtesy of the authorities of the Lewis Institute.

The Council of the Society met at the Lewis Institute at 1.30 P.M. Other members of the Society participated in visits to the works of Messrs. Frazer & Chalmers, the Consumers Ice Company, and the Eisendraht tannery of the American Hide and Leather Company.

The evening session of the Society was held in the banquet hall of the Auditorium Hotel. Dr. W. R. Smith, vice-president of the Society and chairman of the Chicago section, presided. The retiring president, Dr. William McMurtrie, delivered an address on 'The Condition, Prospects and Future Educational Requirements of the Chemical Industries.' After a few announcements the session adjourned, and the visiting chemists enjoyed a 'smoker' given by the members of the local section at the Technical Club, 230 South Clark street.

The session of the meeting on Friday was held in the chemical lecture room of the Northwestern University Medical and Pharmacy School, 2421 Dearborn Street. The meeting was called to order by President McMurtrie at 9.30 A.M.

The annual reports of the Secretary, the Treasurer and the Librarian were presented in order and read by the Secretary. These reports were accepted by the Society and

ordered placed on file. President McMurtrie made a few remarks regarding the thorough work which had been accomplished by the Librarian during the past year, and on motion of Dr. Hart the thanks of the Society were voted to the Librarian for his successful and faithful services.

The editor presented a brief oral report of his work.

Reports received by the Secretary from F. W. Clarke, chairman of the Committee on Atomic Weights and also chairman of the International Committee on Atomic Weights, were presented by the Secretary in the absence of Mr. Clarke, and were read by title and referred to the Committee on Papers and Publications.

The Secretary reported from the Council that that body had considered the question referred to it by the Society at the New York meeting with reference to the passage of H. R. Bill 104, looking to the adoption and use of the metric system, and had decided to recommend that the Society lay the question on the table. By a vote of the Society the recommendation of the Council was adopted and the question was laid on the table.

The Committee on Standards for Instruments of Measure reported progress through Messrs. Munroe and Linebarger, who urged immediate action on the part of the membership with reference to the bill now pending in Congress to establish a National Standards Bureau.

The Secretary presented a motion urging the appointment of a committee to consider the adoption of a permanent badge or pin by the Society. The motion being seconded, it was moved and carried that the whole matter be laid upon the table.

After some announcements W. A. Noyes presented a paper on 'Synthesis of Derivatives of Dimethyl-cylopentanone] and of Beta Beta Adipic Acid and of Alpha Beta Beta Tri Methyl Adipic Acid.' Dr. Noyes also presented a paper by himself and W. M. Blanchard on 'A New Hydroxy Dihydro-campholytic Acid.'

After some other announcements Professor A. B. Prescott presented a paper by B. F. Trowbridge, entitled 'Notes on Sugar Beet Analysis.' This was followed by a paper 'On Hematite Crystals,' by Charles E. Munroe.

The remaining papers on the program were read by titles.

On motion of Dr. Alfred Springer, the thanks of the Society were extended unanimously to the Chicago Local Section; the Local Committee of Arrangements for the meeting, the authorities of the various institutions which had extended courtesies to the Society during its meeting, and the proprietors of the various works which had been thrown open to inspection by the visiting chemists.

The Local Committee made some announcements with reference to a proposed excursion to South Chicago on Saturday morning, and the meeting of the Society was then adjourned. In the afternoon the chemists enjoyed an excursion and visit to the Stock Yards Industries, and at 7 P.M. a subscription dinner was given in the banquet hall of the Auditorium Hotel.

ALBERT C. HALE,
Secretary.

SCIENTIFIC BOOKS.

The Mammals of South Africa. By W. L. SCLATER, M.A., F.Z.S., Director of the South African Museum, Cape Town. Vol. I. Primates, Carnivora and Ungulata. With a map and illustrations. London, R. H. Porter. 1900. Medium 8vo, pp. i–xxx+1–324, with map and 80 text cuts.

Smuts's 'Mammalium Capensium,' published in 1832, a small quarto in Latin, is the first and only attempt to present an account of the mammals of South Africa prior to the work here under notice, of which the first volume has just appeared. Hence the desirability of a good

manual of South African mammals is apparent. This, we are happy to say, is now being provided by Mr. Sclater in the form of a large octavo work in two volumes, beautifully printed and well illustrated with, for the most part, excellent text cuts, many of them prepared especially for the work. The region here included is that portion of Africa south of the Cunene and Zambesi rivers.

South Africa has a comparatively rich mammalian fauna, the three orders here treated—the Primates, Carnivora and Ungulata—numbering 95 species and 8 additional subspecies, while the remaining orders—the Chiroptera, Insectivora, Rodentia, Edentata and Cetacea—to be treated in Volume II., will doubtless raise the number to considerably more than 200. In the present work the author informs us he has endeavored 'to collect together all the information at present available on the subject of South African mammals,' but he has been hampered in its preparation by lack of specimens and by paucity of information regarding the life-history of the species. He has, however, laid a good foundation for further additions and given a most excellent and useful summary of the subject. A bibliography of the more important separate works relating to South African mammals occupies pp. xi–xix, and following the synonymy under each species is a paragraph, under the heading 'Literature,' giving further references.

The work is well designed to serve as a convenient manual, the higher groups being defined, and keys are provided to the genera and species, and the descriptions are fairly full. The text is further paragraphed under 'History,' 'Distribution,' 'Habits,' etc., where whatever is known of the species is briefly summarized.

In respect to nomenclature, it is well to note that the twelfth edition of Linnæus, instead of the tenth is taken as the starting point, and that specific names when employed for genera are discarded in their specific sense, so that we have, for example, *Suricata tetradactyla* instead of *Suricata suricatta*, although the latter is the older name; and *Oreotragus saltatrix* instead of *Oreotragus oreotragus*, etc. As usual with English authors, only two genera are recognized in the family Otariidæ, all the species but one being referred (p. 118) to the genus *Arctocephalus*, the type of which is wrongly given as *A. ursinus;* while the wholly undeterminable name *A. pusillus* (Schreber) is used for the single South African species, instead of the correct name *A. antarcticus* (Thunberg).

This volume is the second in point of issue—Volume I. of the late Dr. Stark's 'Birds of South Africa' being the first—of a 'series in which it is proposed to give an account of the Fauna of Africa south of the Zambesi and Cunéné Rivers,' under the general title 'The Fauna of South Africa,' under the editorship of Mr. W. L. Sclater, the author of the mammal volumes of the series. The second volume of the birds is in course of preparation by Mr. Sclater, from MSS. left by Dr. Stark, who was killed early in the present South African war.

J. A. A.

Report of the U. S. Commissioner of Fish and Fisheries for the Year ending June 30, 1900. By George M. Bowers. Washington, Government Printing Office. 1900. Pp. 191.

The report of the Commissioner of Fish and Fisheries, for the year ending June 30, 1900, again shows an increase of fish distributed of a round hundred million, consisting chiefly of shad, cod, flatfish, whitefish and lake trout. Whitefish, shad and cod stand at the head of the list, the totals being about 337, 265, and 241 millions, respectively. The year, on the whole, has been a good one and the results commensurate with the steady expansion of operations, while local accidents of climate have, in a few cases, reduced the normal output. In California the drought of last year considerably affected the spawning migrations of the quinnat salmon. On the Rogue river, in Oregon, an innovation in the food of quinnat fry, in the way of using canned salmon scraps, was attempted with promising results. In Michigan, the close season was amended to allow the National Commission to take whitefish and lake trout for fish-cultural purposes, with the result of very large collections at a minimum expenditure. The Commission moreover operated the Michigan whitefish hatcheries at Detroit and Sault Ste., Marie, for which the State did not provide

this year. Most of the whitefish output was obtained from 'penned' fish, a method of holding the fish until ripe, which has now an assured place in fish-cultural operations. Seasonal difficulties affected unfavorably the pike-perch in Lake Erie and Vermont, though a total of 90 million eggs and fry was distributed.

The New England stations propagating the great marine food species were unusually successful. Cod were hatched in excess by 50 million of any previous record. The interesting experiment of tagging adult codfish for the purpose of acquiring data on their migrations and growth was continued, 1,311 being returned to the ocean in November from the Wood's Holl Station, of which 11 were captured, some as far south as New Jersey, before the close of the year. A new method was followed in flatfish culture, consisting in allowing natural spawning in tanks in place of fertilizing artificially, the results indicating the superiority of this means of obtaining fertilized eggs of this species.

Three new stations were put in commission—at Bullochville, Ga., Edenton, N. C., and Nashua, N. H., devoted chiefly to the salmonoids, shad and bass, making a total of 35 operated during the year.

The weather considerably shortened the shad season on the Potomac, but an unusual run occurred on the Delaware, the price falling to nearly nothing. The success here and on the Susquehanna made possible a large total output, a gain of several millions over the preceding year. The basses and crappie were in unusual demand, but the development of the collecting work on the Mississippi and Illinois rivers—by which fingerling bass that would otherwise be sacrificed are taken from the 'back' waters of the river, throwing the fish-cultural work upon nature—met all demands at a nominal expense.

Encouraging reports come from Montana and Colorado of the establishment of brook and steelhead trout in waters very recently without these valuable species. Captures of a few specimens in other cases indicate the process of establishing rainbow trout in Maine and Tennessee, Swiss trout in the Adirondacks, and quinnat salmon in Lake Ontario. The Chesapeake and Ohio canal was seined prior to drawing off the water for the winter, for a distance of 92 miles, and some 90,000 fish of many species transferred to the Potomac.

Notable among the biological investigations of the Division of Scientific Inquiry are the oyster experiments at Lynnhaven Bay, Va. These are directed toward a practical method of fattening oysters by the use of a commercial fertilizer through the medium of their diatomaceous food, the diatoms appropriating the fertilizer. The experiments are made in an enclosed and tideless claire and have achieved a definite measure of success in demonstrating the possibility of fattening oysters to marketable condition by this means. The process is slower, however, than demanded for commercial purposes, and modifications of the conditions have been made which provide for artificial currents in the claire, thus approaching more nearly the conditions of nature.

The failure of the North Carolina oyster-beds has been taken up by the Commission, and the steamer *Fish-Hawk* spent the fall and winter on important portions of the grounds. A report upon the subject is in preparation. Eastern oysters have become well acclimatized in San Francisco Bay and support an industry yielding a half-million of dollars annually in mature oysters with the quantity and value on the increase. The conditions at Willapa Bay, Washington, were examined with reference to the fate of a plant of eastern oysters made there in 1894. It appears that the water is colder than is favorable for the setting of the spat. Nothing came of the plant, and while reports show that a large proportion of them were alive a year after planting, the original oysters have now almost entirely disappeared and there is a presumption of depredations upon these grounds. A method of obtaining spat from shallow ponds constructed for the purpose was recommended, the spat to be then planted in the bay. In connection with the failure of eastern oysters to multiply in the colder waters of our northwestern coast, oysters of northern Japan are to be transplanted to Washington waters.

The Wood's Holl laboratory has undergone expansion in equipment, the amount of work done, particularly in devoting, at the suggestion of the Commissioner, the museum room

to the purposes of the library. This change gave great satisfaction to the investigators, who were in greater number than usual. The work carried on included some chemical determinations of the connective tissue of the ocean sunfish, with a view to its value in making glue, and of lobster chitin in the hope of discovering for it a commercial use; diseases of fishes, anatomy of the star-fish, and of the alimentary tract of the flounder; photography and sketching of living marine forms. A series of publications has been planned which is to embrace all the invertebrate groups of the region. The Beaufort, N. C., laboratory completed the first year of its existence and concerned itself, among other things, with the breeding conditions of some fishes, sponges and parasitic crustaceans, the latter including a barnacle (*Dichalaspis*) on the gills of the common blue crab; spawning habits of certain food-fishes; life history of brittle stars; effects of abnormal conditions on the development of oyster eggs and those of other molluscs; the development of a common annelid (Axiothea) which forms part of the food of bottom-feeding fishes, and the food of the hog-fish and croaker. An observation is made on the inferior flavor of the hog-fish taken at Beaufort, which reduces its value as a food-fish as compared with the same species taken, for instance, at Norfolk. One cause of the undesirable flavor is traced to the interesting form Balanoglossus. The Beaufort laboratory is happily located for the purposes of marine biology, and now that a permanent establishment has been authorized by Congress continuous systematic studies on broad lines may be anticipated.

In accordance with the direction of the last Congress, a special lobster and clam investigation, for the purpose of remedying the marked decline in these fisheries, has been instituted. With the lobster, efforts are directed toward methods of rearing the larvæ through the early defenseless stages before liberating. With the clam it is apparently feasible to apply the methods of planting which are so extensively used with the oyster. The work has begun during the past summer and is proceeding satisfactorily.

Some work on variation in the common mackerel, begun in 1898, with a view to the question of its separation into geographical races—a fact demonstrated by an English investigator, Mr. Walter Garstang, for British mackerel—was continued during the summer of 1899, and confirms Mr. Garstang's observation of a marked difference between American and British mackerel. As for recognizable American races the material examined, as far as it goes, tends to show that such do not exist. The data, however, from the extremes of the range of the species are not yet complete.

Collections of aquatic fauna and general biological observations have been carried on in Cobbosseecontee and Sebago Lakes in Maine, in Seneca Lake, New York, in Lake Mattamuskeet, N. C., in West Virginia, in the Wabash Basin, Indiana, and in California, Oregon and Arizona. The biological survey of Lake Erie was carried on as usual throughout the summer, with headquarters at Put-in Bay, plankton studies forming an important part of the work. The collections made by the *Fish-Hawk* expedition to Porto Rico in 1899 have been distributed to specialists in the various groups. The report on the fishes was issued during the last days of the year, the others are approaching completion and it is probable that all will be published during the next fiscal year.

Dr. H. F. Moore submits an outline of the recent extensive cruise of the steamer *Albatross* in the South Seas. This expedition left San Francisco in August, 1899, Mr. Alexander Agassiz in charge of the scientific work, assisted by a party of seven, four of whom represented the Commission. The *Albatross* cruised for over six months among the South Sea Islands, visiting the Marquesas, Paumotus, Society, Tonga, Fiji, Ellice, Gilbert, Marshall and Caroline Islands and Guam. Accounts of the voyage have appeared in these columns. In the Tonga group the trawl was used in 4,173 fathoms, the deepest trawl haul ever made. The work of the party concerned the zoology, geology, ethnology and botany of the island groups, the director devoting himself to the coral formations. The officers of the vessel made surveys and nautical observations. The *Albatross* reached Yokohama in March of the present

year and spent three months trawling and dredging on the coast of Japan. In June she sailed for Alaska on commercial investigations of the Alaska salmon fisheries.

The statistical canvasses have this year covered New England, New York and Lake Erie, and in May the canvass of the Pacific coast was begun. The figures for New England show a moderate falling off in value of fishery products since the last tabulation in 1889, and also in the amount of invested capital, the latter caused by the transfer of the menhaden industry to New York. The lobster fishery has the remarkable record of a diminution, since 1889, of over 50 per cent. in quantity and a coincident increase of over 50 per cent. in value. The total value of New England fisheries reaches over nine and one-half millions. Lake Erie and Lake Ontario come forward with a large increase in quantity and value, the whitefish, a species very extensively propagated by the Commission, sharing largely in this expansion. Over three and one-half million pounds of the much-abused carp were taken from the American waters of the lake in 1899, with a value of over $50,000. Indeed, a glance at the figures for this species shows that the carp is certainly the most valuable fresh-water fish after the whitefish and its allies, the pike perch and the lake trout, and should afford food for thought to those who condemn the carp as an unmitigated evil. The Illinois Fisherman's Association reports the catch in the Illinois river as greater in quantity than that of all other species combined, with a value of nearly $200,000. Carp have increased many fold in the Middle Atlantic States and the Middle West during the last decade, the quantity taken in Lake Erie, the Illinois river, and the Ohio river and its tributaries, during 1899, being nine times that of six years ago.

The annual visit to the fur-seal rookeries on the Pribilofs shows the continued decline of the seal herd as a consequence of the continuance of pelagic sealing. The number of seals taken from the islands under government supervision was 16,812, and the pelagic catch from the American herd some 34,000.

M. C. MARSH.

A Handbook of Photography in Colors. By THOMAS BOLAS, ALEXANDER H. K. TALLENT and EDGAR SENIOR. Published by Marion and Co., London. American edition by E. & H. T. Anthony, New York and Chicago.

The authors of this book have brought together in compact form the very scattered literature pertaining to color photography. Part I., by Mr. Bolas, contains a brief history of helichromy, from the early work of Seebeck, Herschel and others until the present day, covering about the same ground as the new edition of Zenker's 'Lehrbuch der Photochromie.' His account of Wiener's work and suggestions regarding the possibility of getting a truly chromo-sensitive surface will be found of use by any who are engaged in the hitherto fruitless search of a substance which when exposed to colored light will assume permanently the color of the illuminating light. That such a surface is theoretically possible is clearly shown, and methods of realizing it in a crude way are given.

The general principles of the various processes are given, including those of Joly, Ives, Lippmann and others. Lippmann's account of his interference process as delivered in English before the Royal Photographic Society is given verbatim. His picture of the formation of the thin laminæ which produce the colors by the stationary light waves is interesting. It will be remembered that these stationary waves are produced by backing the sensitive film with mercury. "If you put no mercury," says Lippmann, "each train of waves rushes through the plate and wipes off every record of its own form by reason of its velocity; you cannot expect a thing which moves with a velocity of 300,000 kilometers a second to give a photograph of itself. If you put a mercury mirror behind the plate, then the following phenomena occur: the light is reflected back on itself; the light rushes in with the velocity of light, and rushes out with the same velocity; the entering and issuing waves interfere, and the effect of interference is that vibration takes place, but the effects of propagation are stopped, and instead of having propagated waves, we get stationary waves; that is, the waves

now rise and fall each in its own place; they pose, therefore, in the film and impress their form upon it, the largest movement giving the largest impression, and where the movement is naught the impression is naught."

Part II., by Mr. Tallent, is devoted to three-color photography. It opens with an elementary treatment of spectrum work as applied to the study of color and color mixtures. Following this comes a very complete account of color curves, and the reproduction of various colors by the synthesis of three primary spectrum colors. Ives's beautiful method is again described, together with fuller details regarding the preparation of color records, the preparation and use of color filters and other details. The various other modifications of the three-color scheme are treated, closing with a chapter on Wood's diffraction process. It seems a pity that fuller working details of some of the methods of producing colored transparencies by the superposition of dyed films, are not given. However, there are hints enough to enable one to experiment along these lines if so inclined.

Part III., by Mr. Senior, is a dozen or so pages on the Lippmann process, with formulæ for the preparation of the emulsion. There is a good deal of repetition in the book, as is usually the case in symposia of this sort. It will, however, be found very useful as a reference book by those desirous of experimenting with any of the processes.

SCIENTIFIC JOURNALS AND ARTICLES.

THE January *American Journal of Physiology*, the concluding number of Vol. IV., records in the initial paper further interesting results obtained by Loeb in his study of artificial parthenogenesis. Loeb has caused the eggs of Chætopterus, an annelid, to develop into free swimming larvæ by simply placing the eggs in various solutions which cause them to lose water. Potassium ions, however, have peculiar power over these eggs which grow to the trochophore stage in a KCl solution with an osmotic pressure considerably lower than that of sea water. A slight addition of HCl to the sea water also causes the eggs to develop. Loeb carefully observed the morphological changes in the eggs during their development, and found that although the artificially produced trochophores may be indistinguishable from those arising from fertilized eggs, yet the processes of segmentation varied so greatly that these processes must be regarded as distinctly a function of the constitution of the sea water. These observations, together with those on the formation of giant embryos by the fusion of two or more eggs, have an important bearing on developmental mechanics and cell lineage. Loeb concludes with a consideration of the relation

between natural and artificial fertilization, and of the relation of his results to the theory of fertilization and of life phenomena in general. 'The Theory of Phototactic Response' is a clarifying paper by Holt and Lee. They aim to show that organisms do not react to direction of light as well as to intensity of rays. The conditions of the organism itself must be more closely regarded. Every ray impinging on an organism stimulates it at one point and in proportion to the intensity. If the light comes to one side of the organism, that side is naturally stimulated more than the other and the response is thus determined. The two factors, intensity of light and the side of the organism the light reaches, account for all the phenomena included under phototaxis and photopathy. Reaction to the 'direction of the ray' must, therefore, be regarded as an incorrect conception, and the term phototaxis relieved of that meaning. A. P. Mathews presents a paper on the spontaneous secretion of saliva, which brings evidence against the theory of secretory nerves. On readmitting blood to the dog's submaxillary after having cut off the supply for 12 to 25 minutes, the gland secretes rapidly. This secretion is not due to nerve cells in the gland, since nerve cells are made ineffective by absence of blood supply during so long a period. The important fact is that atropine stops the secretion ; it must act directly on the gland cells. The value of this drug therefore as a witness for secretory nerves is seriously impaired.

The Journal of the Boston Society of Medical Sciences for November 20, 1900, opens with an article on 'Ergographic Studies in Muscular Fatigue and Soreness,' by Theodore Hough. T. M. Rotch notes the 'Treatment of the Proteids of Cow's Milk' and J. J. Thomas decribes, with illustrations, 'Five Cases of Injury of the Cord resulting from Fracture of the Spine,' showing among other things the difficulty of exactly locating the seat of injury and the necessity of taking into consideration the manner in which the accident took place. It is noted that early operations should be limited to cases where the neural arches are thought to be crushed and cases of knife and bullet wounds. John Dane notices 'Some Variations in the Skeleton of the Foot,' stating that some form of variation from the type of foot described in our anatomies may be expected in thirty-three per cent. of human feet.

The Popular Science Monthly for December has for its first article a paper by S. F. Peckham on 'Asphaltum for a Modern Street' telling what the material is, where it is found and how the deposits are worked. Allan Macfadyen discusses 'The Effect of Physical Agents on Bacterial Life' showing the varying effects of light, air and temperature on these simple organisms, and stating the remarkable fact that typical series of bacteria were subjected to the temperature of liquid hydrogen—250° C.—and that upon being thawed their vitality was unimpaired. L. O. Howard treats of 'Flies and Typhoid Fever' and shows the danger of infection from several excreta-frequenting species and Edwin S. Crawley has an interesting article on 'Geometry: Ancient and Modern,' Huxley's 'Address given before the Anthropological Department of the British Association, 1878' is reprinted. It is not republished in his 'Collected Essays.' William Henry Hudson gives a brief abstract of the little known 'Story of Autonous' and 'The Economic Life of France' is considered by Edward D. Jones who notes the physical conditions of various portions of that country and their related industries. Pearson's 'Grammar of Science' is unfavorably criticized by C. S. Peirce in a series of annotations on the first three chapters, and in the instalment of 'Chapters on the Stars' Simon Newcomb discusses the structure of the heavens and the distribution of the stars. Under discussion and correspondence an editor utters a well-founded protest against needless obscurity in scientific publications.

THE opening article of *The American Naturalist* for December is on 'The Study of Mammalian Embryology,' by C. S. Minot, and is a preliminary publication of portion of a text-book on which the author has been at work for a considerable time. The general plan of the work is outlined and samples are given of the fine wood cuts with which it is to be illustrated. Henry F. Osborn presents a third paper on 'The Origin of the Mammalia: Occipital Condyles of Reptilian Tripartite Type,' the con-

clusion being that the reptilian tripartite origin of the mammalian condyle is more probable than the amphibian dicondylic origin. T. W. Galloway presents some 'Studies on the Cause of the Accelerating Effect of Heat upon Growth' giving the results of experiments upon the larvæ of various amphibians and showing that all the early developmental processes were accelerated. C. B. Davenport discusses 'The Variation of the Statoblasts of *Pectinatella magnifica*' and J. B. Johnston describes 'A Sealing Stone Jar for Zoological Laboratories' which seems very useful and is sealed with a heavy paraffin oil. The title page and index of the completed thirty-fourth volume are included in this number.

On January 1st appeared the first part of 'Geologisches Centralblatt, Revue Géologique, Geological Review,' edited by Dr. K. Keilhack, Bingerstrasse, 59, Wilmersdorf, Berlin, and published by Gebrüder Borntraeger, Leipzig, at an annual subscription of 30 Marks. The American agent is G. E. Stechert. The review is to appear on the 1st and 15th of each month, and is intended to give short, uncritical notifications of the latest publications in geology and allied sciences. The abstracts are written in German, French or English, according to the language in which the original papers have appeared. Since the contributors are to be compatriots of the respective authors, this renders their task easy; but the converse method would be of more advantage to scientific workers, and unless the German printers are more careful than they have been in the first number, even the English will be unintelligible to readers in this country. There can be no doubt as to the 'uncritical' nature of the notices; but this may be carried too far. It is to be hoped that authors, by contributing their own abstracts, will forestall some of the mangling to which they are otherwise liable.

It is interesting to note that in the numerous surveys of the nineteenth century, now being published, science usually occupies about half the space. This is in curious contrast to the slight attention paid by the newspapers to contemporary science and the carelessness with which scientific news is usually complied. Several of the daily papers have published very good historical surveys of the progress of science during the century; thus the New York *Evening Post* of January 12th, contains articles on astronomy by Professor Newcomb, on physics by Professor Lodge, on electricity by Professor Trowbridge, on medicine by Dr. Billings and other interesting articles. The New York *Sun* is also publishing a history of the nineteenth century in thirteen articles of which nine are on the science as follows: 'Evolution' (Dec. 23), by Alfred Russel Wallace; 'Chemistry' (Dec. 30), by Professor W. Ramsay; 'Archeology' (Jan. 6), by Professor Flinders-Petrie 'Astronomy' (Jan. 13), by Sir Norman Lockyer; 'Philosophy' (Jan. 20), by Dr. Edward Caird; 'Medicine' (Jan. 27), by Professor William Osler; 'Surgery' (Feb. 3), by Professor W. W. Keen; 'Electricity' (Feb. 10), by Professor Elihu Thomson; 'Physics' (Feb. 17), by President F. C. Mendenhall.

SOCIETIES AND ACADEMIES.

ZOOLOGICAL CLUB OF THE UNIVERSITY OF CHICAGO.

At the meeting of November 14th, Mr. G. A. Allen reviewed a recent paper by Duneker on variation in *Palæmonetes*, and Miss Minnie Enteman recounted her observations on the behavior of *Polistes*. Some of the more important points of the latter paper may be mentioned here:

Polistes, our common paper wasp, constructs for a nest a single flat plate of hexagonal cells without an external covering. This renders observation of its habits and instincts very easy. Among the facts gathered concerning the activities characteristic of the larval, pupal and imaginal life, the most interesting relate to those of the newly excluded worker:

1. Fear is very generally exhibited, the young worker retreating precipitately when a strange object is presented to it. This gradually diminishes with the repeated appearance of the awe-inspiring object. If the bit presented is edible the worker will, after five or six trials, come up, touch it with the antennæ and exhibit

2. The feeding instinct. This consists in crushing the food in the mandibles, and ex-

tracting its juices, which are then swallowed by the worker. When the mass has reached a pulp like consistency it is distributed to the feeding larvæ which occupy the cells of the nest. This habit has been thought to arise by imitation of the queen or an older worker, but that it is independent of such example is proved by the fact that it is acquired in all its perfection by wasps which have had no association with others of their kind.

3. The locality study. This is a mere desultory alternation of short flights and strolls, by means of which the wasp comes in contact with objects surrounding its nest. It appears to use these objects to some extent as landmarks, but experiments indicate that the olfactory sense is also an important factor in guiding it.

4. In a way the wasp remembers. This is indicated by its behavior when a change is made in its nest, and also by its accustoming itself to the appearance of strange objects.

5. Wasps learn nothing from one another. Instinct and individual experience account entirely for their complex activities, and their apparent cooperation is due to the accident of being born in the same nest.

At the session of November 28 Mr. C. M. Child gave a brief account of some zoological observations made during a recent trip to Florida, and showed a number of specimens.

Following this, Mr. E. R. Downing discussed 'Recent Experiments on Sea-Urchin Eggs,' referring chiefly to the work of Driesch.

The last session of the club for the autumn quarter was held December 12. This was devoted to a paper by Mr. C. C. Adams, entitled 'Geographical Distribution of Variations in *Io*.' The paper was illustrated by a number of lantern-slides, showing series of the shells from different localities.

The following abstract gives an outline of Mr. Adams's work on this form:

The gasteropod genus *Io* is found only in the headwaters of the Tennessee River and its tributaries. By the aid of a grant from the American Association for the Advancement of Science the Clinch and Powell Rivers were explored and the following facts concerning its geographical distribution and variations were discovered:

These shells are remarkably variable, all intermediates being found between a smooth shell (*Io fluvialis* Say) and a very spinose shell (*Io spinosa* Lea). The extremes of variation do not occur promiscuously in all localities, but are quite definite in their occurrence. In the headwaters of both streams the smooth shells form the dominant population, but farther down stream, in the case of the Clinch River within 60 miles, the entire shell population changes from a smooth to a very spinose shell. In the intermediate region the shells are mixed, smooth, spiny and intermediate.

The headwater shells in the Powell are more globular and relatively stable, have low or no spines, distance between spines small and slightly variable. Down stream the shells are less globular and relatively variable, spines high and fairly stable, distance between spines wide and variable.

In the Clinch the headwater shells are more globular (similar to those in the head of the Powell) and relatively variable, low or no spines, distance between spines small and slightly variable. Down stream the shells are less globular and relatively stable, spines are high and variable, distance between spines wide and stable.

Thus these parallel streams have parallel differences in their *Io* shells.

C. M. CHILD,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE U. S. NAVAL OBSERVATORY.

TO THE EDITOR OF SCIENCE: Every reader of SCIENCE must have been greatly interested in two recent editorials discussing the Naval Observatory at Washington and its work, but many of them will regret that where so much is said and so well said, the real meat of the controversy is left untouched, although in the last paragraph it seems to be 'scented.' Is it not true that the question in the minds of most thoughtful people is—what, in the name of reason is the use of having the Observatory for astronomical research under the Navy Department, any way?—why not just as well a geological survey? If this question be pertinent it cannot be impertinent and why do scientific

men continue to beat about the bush when they know exactly where the real quarry is?

A few years ago the pressure for a reformation in the management grew to considerable proportions and it was shrewdly met by the Navy Department in the scheme for an astronomical director. Many hopeful people without much experience rejoiced at this which they thought was a great step in the right direction. When a year or two ago the continued dissatisfaction had grown to the extent of demanding the appointment of committees by the American Association for the Advancement of Science and the Astrophysical Society, it was again as shrewdly encountered by the appointment, by the Secretary of the Navy, of the Board of Visitors whose report is unhappily meeting with criticism fore and aft. A distinguished statesman whose loyalty to the interests of the Navy Department has long been known was made chairman of this Board and it is an open secret that he peremptorily cut off all suggestions looking to the real emancipation of this great institution.

The scientific members of the Board, all most excellent astronomers, but possibly not well informed as to the methods sometimes resorted to by great statesmen, were restricted in the recommendations to proposals for repair rather than reconstruction. In spite of their limitations they succeeded in getting in a most interesting and valuable report—one in which symptoms are admirably set forth, although there is 'much silence' as to the real nature of the complaints. Is it not perfectly true that the Naval Observatory, as such, has been of little value to astronomical science, although *astronomers* attached to the establishment have contributed greatly to the glory of American science? But this is in spite of, not on account of the character of the administration of the Observatory. This administration is and must always be, and properly so, while it is under the Navy Department, military in its character. The utter incompatibility of this sort of control and direction with the best interests of scientific research needs no demonstration. The very existence of a comfortable retiring pension for astronomers who survive their sixty-second year has been unfortunate in its results, in that it has led to the appointment, through the use of influence, other than that of merit, of men whose principal ambition was old age under these conditions. Why should a regularly appointed astronomer be detailed as inspector of apparatus for fire protection at the Navy yards? What would be thought of a civil establishment which detailed one of its best paid professors of astronomy to the duties of superintendent of grounds and buildings? M.

REPRODUCTION OF DIFFRACTION GRATINGS.

To the Editor of Science: The communication of Professor R. W. Wood in your issue of January 4th (p. 33), concerning diffraction gratings, is of interest to me. I have, during the past year, made some experiments on the reproduction of gratings. Obtaining through the kindness of Professor Rowland and Mr. Schneider, a fine flat glass grating, it was silvered on its face in a silvering solution, then electroplated with silver and afterward with a heavy coat of copper. With care it could be readily removed from the glass especially if warmed. I had used the process to make concave mirrors from lens surfaces about six or seven years ago and the results were excellent, even the most minute scratches or imperfections of the glass appearing in the silvered surface with the utmost fidelity, while the polish and brilliancy was such that one could scarcely believe that the surface was not one of glass instead of polished metal. With the glass grating the experiments gave excellent reproductions of the ruling and great brilliancy, but the surface of the metal grating was not optically flat but slightly warped. This condition varied in different trials and the result would probably have been more perfect if the temperatures during the electro-depositing had been maintained rigorously the same.

It is possible that had the glass been convex the resultant concave grating would have been without distortion. Lack of time has so far prevented my trying another expedient which ought to give good results. It is to first silver the glass grating as before, then, having coated a flat glass surface with a thin layer of adhesive cement, like hard pitch or shellac warmed, or with a cement like glycerine and litharge which

sets firmly, apply this to the silver surface and allow it to harden. It should then be easy to remove the silver grating from the glass grating and the reproduction should have all the gloss and accuracy of the surface serving as the matrix. My interest in the matter was the possibility of easily and rapidly obtaining fairly good gratings without great expense, so that students in laboratories might use them without restraint. From one good glass grating numerous reproductions could be had at any time.

ELIHU THOMSON.

SWAMPSCOTT, MASS.,
Jan. 5, 1901.

THE FRICTIONAL EFFECT OF RAILWAY TRAINS ON THE AIR.

AN interesting and in some respects exceptionally important paper, read by Professor F. E. Nipher before the St. Louis Academy of Science has just been published by that Society in its transactions.* In this paper, the results of an experimental investigation of the effect of railway trains in the production of air-currents, and in causing the motion of adjacent bodies, are given with tabulated and diagrammed data. The effect of a rapidly moving express-train in producing strong air-currents is familiar to all who have seen anything of that kind of train-service, and the results of action of these fast-moving currents in overturning and in transporting objects near the track are hardly less familiar; but this is the first investigation conducted in a scientific and satisfactory manner to determine the quantitative measures of such effects. The stimulus to this particular research seems to have been the denial, by the Supreme Court of Missouri, that such effects are or can be produced.†

The station agents of all the great trunk-lines of railway over which fast trains are operated are invariably cautioned regarding this danger and are careful to warn people against standing near the track when an express train passes. Small articles, and especially bulky and light merchandise, may often be seen to move under the 'suction' so produced, and, in the case referred to, a boy standing near the track, awaiting the passing of the coming fast train, and about to cross, was overthrown and rolled under the wheels and killed. The evidence showed that he was not struck by the train and the upper part of his body was not bruised. 'He fell after part of the train had passed.' The Court, however, repudiated the evidence of two scientific men of recognized attainments and distinction, testifying to the existence of known facts and to the probability of the claim of the plaintiffs in the case. The outcome of this doubt of the evidence was the employment by Mr. Nipher of a large part of the succeeding summer in the investigations here recorded, which were carried on, on the various roads leading out of St. Louis to Burlington, Chicago and Cairo. The Illinois Central Railroad finally fitted up a special car for the work; this was employed in securing the larger part of the information published.

The difference of pressure was taken between the interior of the car and some one point, selected by the observer, in making a series of observations from contact with the side of the car to a stratum several feet from the side, and the successive differences of pressure constitute measures of the varying tendency to carry along loose bodies near the track and of the tendency, also, to rotate them. A cup-shaped collector was used and the Newtonian equation was adopted. The coefficient, for pounds per square foot and miles per hour, was found to be 0.0025, very nearly, without wind. Still air is only reached at distances of sometimes many feet from the side of the train. The curve of varying pressures relatively to the car was found to be, as plotted, approximately hyperbolic, the vertical asymptote finding its position a short distance inside the car. The pressures measured range from 3.4 to 6 pounds on the square foot, at distances of 0 to 30 inches from the side of the car; the mean speed being 38 to 46, usually about 40, miles an hour; at which speed the

* The Frictional Effect of Railway Trains upon the Air; Francis E. Nipher. *Trans. Acad. of Science of St. Louis;* Vol. X., No. 10. Issued Nov. 12, 1900.

† "When the case was tried a second time, and again resulted in a verdict against the company, the Supreme Court attacked the experts it had approved in the first reversal and threw out their uncontested evidence. * * * The Supreme Court of Missouri decides that the physical laws of the universe do not exist, so far as that august assemblage is concerned." —*St. Louis Mirror*, November 29, 1900.

head-pressure relatively to the earth would be about four pounds per square foot. Light winds, sometimes following, sometimes resisting, the train, caused some variations which were allowed for in computations.

It is to be noted that a plane surface would have given a higher resistance, by at least 50 per cent., than was recorded by the cup-shaped vane. R. H. T.

TRIVALENT CARBON.

IN the *Journal of the American Chemical Society* for November appeared an article of very unusual interest. By the action of silver, mercury or zinc on triphenylchlormethane Dr. M. Gomberg has obtained a new hydrocarbon, *triphenyl-methyl*, $(C_6H_5)_3C$. For some reason, perhaps because of space relations involved, two molecules of this hydrocarbon do not unite to form hexaphenylethane, $(C_6H_5)_3C-C(C_6H_5)_3$, as would be expected. The new body is the only one among the seventy thousand or more compounds of carbon, which contains an odd number of atoms of odd valence. The compound furnishes the first opportunity of studying the properties of a substance containing a carbon atom that is almost certainly trivalent. From this standpoint, as well as others, the discovery possesses a great theoretical interest. Especially the properties of triphenyl methyl in its rapid absorption of oxygen furnish a practically complete refutation of the view that benzene, ethylene and similar compounds contain trivalent carbon. W. A. N.

COLUMBIA UNIVERSITY.

THE trustees of Columbia University have authorized the publication of the following statement drawn up by President Low:

The problem of Columbia University can now be defined, for the first time since, in 1892, it was determined to move to Morningside Heights.

Cost of land and development at Morningside Heights,	$6,516,300 17
Improvements at College of Physicians and Surgeons,	879,688 43
	$7,395,988 60
Interest to June 30, 1900,	586,519 92
	$7,982,508 52

Of this large sum the University has succeeded in paying, mostly out of gifts and legacies, $4,250,000. Of its outstanding debt the sum of $750,000 is provided for. It still owes $3,000,000 that is not provided for; upon which the annual interest payable is $98,500.

Careful computations justify the undersigned in saying that eight years from now the University will be able, by the increase of income from its fees and endowments to care for its floating debt without embarrassment to its educational work. The falling in of contingent interests already definitely established may hasten this result importantly. Experience also demonstrates that the endowments of the University are likely to be constantly increased by gift and legacy year by year.

The problem of the University, therefore, is to conduct its educational work for a period of eight years without curtailment by reason of the interest to be paid in the meanwhile on its outstanding debt, say $100,000 a year.

For the academic year ending June 30, 1897, the last year at the 49th street site, the University had a deficiency on its current educational account, disregarding interest, of $48,260. For the coming academic year, 1901–1902, the estimates for the Budget already made show that the ordinary income of the University next year will pay all of its current expenses except the interest on its outstanding debt.

If our interest payable can be taken care of for eight years, the problem of the University growing out of its removal to the new site will be solved.

From the purely business point of view, the operations of the University have been already justified. Its plant has been increased in value, after deducting the proceeds of its old buildings, by more than $6,250,000, taking its new site at cost. If the new site be taken at its present market value, the increase in the value of the University's plant would be not less than $8,000,000. The debt incurred in producing these results, still remaining unprovided for, is only $3,000,000. In addition, University Hall is now being enlarged by gift; and Earl Hall is about to be erected, also by gift. In the same interval, the trust funds of the University have been increased by $1,250,-

000; the library has grown from 120,000 volumes to over 300,000 volumes; the teaching force from 226 to 361; and the number of students from 1,564 to 2,560. These figures do not include either Barnard College or Teachers College.

Since removal, also, an educational deficiency of more than $48,000 has been overcome, and the University, after this academic year, will be running within its income, after assuming the full care of its enlarged plant.

For a few years and for a few years only, the University needs help to prevent its debt from being further swelled by borrowed interest. It is not possible to take any such sum as the University needs, annually, in the immediate future, out of its educational work, without destroying its efficiency. This ought not to be be permitted: First, because the work is highly useful and is being economically and well done; second, because any curtailing of the University's educational offer would be reflected immediately in loss of earning power; and, third, because, for the credit of the city, the University must be kept where it now is, in the very front rank.

To meet this situation, appeal is made to all the friends of the higher education in New York. Friends of the University, including the President and Trustees, have already pledged $38,000 for this purpose. For the rest, the University confidently turns to the citizens of New York who value the things for which Columbia University stands in this metropolitan city.

REPORT ON A WESTERN BRANCH OF THE AMERICAN SOCIETY OF NATURALISTS.

As we have already announced, the American Society of Naturalists decided to meet next year at Chicago, and the Council was requested to report on the relations of the Society to the Western Branch, which has held two successful meetings in that city. Prior to this decision a committee consisting of Professors Henry Kraemer, G. D. Macloskie, E. B. Wilson, C. B. Davenport and T. H. Morgan made a report which we publish, in order that men of science may have an opportunity to consider and discuss a problem of considerable importance. The report of the committee is as follows:

The Committee appointed to consider the proposition offered by some of the members of the American Society of Naturalists to form a Western Branch of this Society (See Records of A. S. N., p. 29) submit the following recommendations for the action of the Society:

1. The American Society of Naturalists appreciates the desire of some of the Western members to form a Society of the Central States and, furthermore, appreciates the motives of the members to make this new Society a branch of the American Society of Naturalists. It is doubtful, however, if it will be possible to form such a branch, and if such a society is formed, we believe it should be as a distinct organization having its own officers, control of its own finances and the publishing of its own records.

2. The original intention of the Society of Naturalists was a good one, but we believe that it was unfortunate in changing its name from 'Society of Naturalists of the Eastern United States' to 'American Society of Naturalists' and in limiting the meetings to the Eastern United States. We recommend, therefore, that the original name be readopted in place of the present name. We believe this action would tend to facilitate the formation of similar societies, if desired, in different parts of the United States, and be in accord with the inception principles of this Society.

3. It is further recommended, in order to strengthen the work of naturalists in the United States, and so add to the influence of the whole body of naturalists in this country, that, if a Society of Naturalists of the Central United States be formed, or any similar society, if possible, each society appoint delegates to represent it at the Annual Meeting of the Sister Society; that the Executive Committee of the one cooperate with the Executive Committee of the other for united effort in contributing to the support of different objects such as the Naples and Wood's Holl Biological Stations; and that the societies extend to each other mutual privileges and courtesies such as: (*a*) Change in membership from one society to the other by approval of the Executive Board of both societies; (*b*) Admission of members of both societies to the meetings of either society, with enjoyment of certain privileges such as the reading of papers, taking part in the discussions and participation in such other matters as may be deemed advisable.

SCIENTIFIC NOTES AND NEWS.

MR. JOSEPH WHITE SPRAGUE, of Louisville, Ky., who died recently in Switzerland, left a will that should ultimately greatly benefit the

Smithsonian Institution. It gives 85 per cent. of the interest on the estate to relatives for life. On their death the entire property, increased by 15 per cent. of the income to be laid by each year, is held in trust for twenty years, and then reverts to the Smithsonian Institution. One-half of the annual income is then to be added to the principal each year, and the other half is to be used for the advancement of the physical sciences by prizes, lectures or original research. It is estimated that the fund now is worth $200,000, and that it will be available in about fifty years.

A BILL has been introduced in the House of Representatives directing the general government, through the Secretary of the Interior, to secure title to the cliff dwellers' region of New Mexico for park and scientific purposes, and one in the Senate appropriating $5,000,000 for the purchase of land in the Appalachian Mountains for a national forest reserve.

THE Washington Academy of Sciences is endeavoring to secure a permanent home for the Academy and the nine local societies which are affiliated with it. A lot has been purchased on 15th Street, between L and M Streets, northwest. It is hoped that funds enough can be secured to warrant the erection of a building containing a large hall for various public meetings and small rooms for the different purposes of the various societies.

DR. H. R. MILL will, as we learn from *Nature*, join Mr. Sowerby-Wallace in carrying on the British Rainfall Organization, in continuation of the work of the late Mr. G. J. Symons.

WE regret to learn that the *Philadelphia Medical Journal* will no longer be edited by Dr. George M. Gould. The Journal has been edited by Dr. Gould since its establishment and has been made by him one of the half-dozen valuable medical journals of the United States.

IN commenting on the election of Professor W. W. Campbell to the directorship of the Lick Observatory, the *Astrophysical Journal* says: "The wisdom of this choice will be apparent to every one familiar with the circumstances of the case. The task which falls to the successor of Professor Keeler is no easy one, a fact which the Observatory Committee fully appreciated. They accordingly deferred action until the opinions of many eminent astronomers in this country and abroad could be secured. The replies, almost without exception, named Professor Campbell as first choice. It is evident that his remarkable success as an investigator, his tireless energy and his ability to direct the works of others are widely known and appreciated. It is a pleasure to extend congratulations to the President and Regents of the University of California for the wise manner in which the appointment was made; to the Lick Observatory for its bright prospects under such leadership, and to Professor Campbell himself for the wider opportunity in the prosecution of his researches which he will now enjoy."

DR. W. WALDEYER, professor of anatomy at Berlin, has been elected a member of the Moscow Natural History Society.

IT is understood that Lord Kelvin will give an address on the textile industries at the annual dinner of the governors of Yorkshire College, on February 1st.

A MARBLE bust of Friedrich Gustav Gauss is to be made and placed in the lecture room for geodesy and mathematics at the University of Berlin.

THE death is announced on December 30th of Mr. William Pole, F.R.S., formerly professor of civil engineering in University College, London, an eminent writer on engineering subjects and an active member of a number of Government commissions of inquiry. He was a man of wide interests, being a gifted musician and student of music and the author of the well-known 'Evolution of Whist.'

WE also regret to learn of the death of Mr. Philip Crawley, fellow of the Zoological and Linnean Societies of London, and the possessor of collections of birds' eggs and butterflies, said to be among the finest in the world; of Mr. F. R. Bedford, a young English zoologist, known for his studies on the echinoderms, and of Senhor Cordeiro, Secretary of the Portuguese Geographical Society.

THE Chicago Medical Society has adopted a resolution protesting against the duty of 20 per cent. on pathological specimens.

IN accordance with the recommendation of Governor Odell, a bill has been introduced in the New York Assembly abolishing the present Forest Preserve Board and transferring its duties to a Forest, Fish and Game Commission. This Commission would have a president with a salary of $5,000 and two other members appointed from the commissioners of the Land Office without extra salary.

As a part of the work of the Geological Survey in Alaska this year, an arctic party will proceed from Bergman on the Koyukuk River by the Allen Kakat River to the divide, then down some stream to the arctic coast and along the coast southward and westward. Another party will go westward from Bergman down the Kowak River to Kotzebue Sound. Another party will continue investigation of the Copper River region.

WE learn from the *Irish Naturalist* that Professor A. C. Haddon, and Messrs. H. J. Seymour, R. L. Praeger and Halbert, have been investigating the Cave of Dunmore in County Kilkenny, Ireland, both as regards its geology and its past and present fauna, and have taken a number of the small animals which render the Mitchelstown cave so interesting.

A COLLECTION of marine, fresh-water and land shells, made by the late Sir James Emerson Tennent, Governor of Ceylon, has been presented to the Municipal Museum of Belfast, Ireland, by the executors of the late George Horner, who had purchased it from a previous owner.

THE Hon. E. S. Converse has given $125,000 for an endowment fund for the Malden Public Library, established by him.

THE daily papers report that the Finlay theory of the propagation of yellow fever by mosquitoes has been further confirmed by the commission now studying the subject in Cuba. Cable dispatches state that a monkey which had been bitten by an infected mosquito developed on the fourth day well-marked symptoms; that of six non-immunes bitten by mosquitoes which had previously bitten yellow fever patients, five developed yellow fever, while subjects who slept in infected clothing and bedding, but were guarded from mosquitoes, were untouched.

THE plague has broken out at Vladivostock with nineteen cases of which fifteen have been fatal.

ON the afternoon of December 7, 1900, there passed over northern Colorado and southern Wyoming a magnificent fireball, which was so brilliant that some observers described it as rivaling the sun. It exploded when passing over North Park, Colorado, its detonations inspiring animals with terror and startling people. Some reports state that the earth was shaken and windows in houses broken. The Chamberlin Observatory has sent circulars broadcast over the State and has utilized the newspapers thoroughly in an endeavor to gather information. The data obtained have been placed in the hands of Miss Lela L. Stingley, of the University of Denver, for discussion and publication.

MR. A. G. S. JOSEPHSON, of the John Crerar Library, submitted, at a recent meeting of the Bibliographical Society, of Chicago, a plan for a complete bibliography of American literature on cards, thus making it possible to issue to subscribers, during the course of its preparation, cards for either the whole work or for any part thereof. The plan provides for the organization of a Bibliographical Institute, either specially endowed or supported by contributions from scientific societies and institutions. The Society voted that a committee of three be appointed to consider ways and means for carrying out the plan, and the President, Professor Camillo von Kleuze, appointed as members of the committee Messrs. Clement W. Andrews, Frederick H. Hild and Carl B. Roden.

IN the spring of last year the London *Times* published a series of articles on American engineering competition that attracted much attention. The articles are now being continued, and it is sought to explain the growing place taken by American manufactures throughout the world, including Great Britain. Apart from the natural resources, the chief factors are said to be the placing of young men in charge of important enterprises and the educational methods. The technical schools, though highly

praised, are said to be no better than those in Great Britain, but in regard to secondary education the article proceeds: "So far as I can see, the American system is more truly educational, less pedagogic; the child is made to learn, I will not say things that are useful, but things that more develop his intelligence and reasoning faculties. I think any average Englishman of middle age, whether of a public or private school, who looks back on his school days must be struck by the vast amount of time and tears he spent in acquiring knowledge which he has entirely forgotten. "But the acquiring of this knowledge," it is said, "has developed his reasoning powers and strengthened his memory." The latter, no doubt, is true, and no one would undervalue memory. But the memory so acquired is of a description that is the least useful in the business affairs of life. Let us take a single example. Perhaps the most marvelous exhibition of memory is that displayed by players of blindfold chess; but who would select a man, because he was an expert in this science, to conduct a business? In regard to the claim of development of reasoning powers, it may be that the absolute reverse is the truth, and to learn by rote things that have no meaning to the learner is possibly the surest way to stunt the intellect. The most valuable intellectual gift a man can possess—I speak with all deference, not as an educationist, but as an engineer—is the power of concentrating his mind on the problem immediately before him; and the learning of meaningless or objectless things—they need only be meaningless or objectless to the learner—is the surest way to cultivate a discursive mental habit. Let any one who doubts this watch an average school boy getting by rote a Greek verb or any other lesson equally empirical. The most trifling incident will distract his attention, and that not from wilfulness, for the penalty of not knowing his lesson has many real terrors. Educational methods, I know, have improved and are still improving in this country, but when all is said I attribute the greater mental alertness of Americans, especially American middle-class youths, to the lead that American schools have taken in this respect.

UNIVERSITY AND EDUCATIONAL NEWS.

According to press despatches, Professor E. A. Ross, lately professor of sociology at Leland Stanford Junior University, has been appointed professor in the University of Nebraska and Professors G. E. Howard (history), William H. Hudson (English literature) and G. N. Little (mathematics) have resigned their chairs at Stanford University.

The latest benefaction of Dr. B. K. Pearons's is reported to be $200,000 for Beloit College, conditional on the raising of $150,000 more by June 15th.

Warren A. Wilbur, of South Bethlehem, has given $5,000 to Lehigh University for the equipment of a mechanical laboratory.

An anonymous gift of £50,000 has been made to the Woman's Agricultural College at Reading, England.

In order to limit the crowding of the medical profession in Germany, the Government has introduced a bill regulating entrance to the medical profession, prolonging the period of study to five years and enlarging the subjects upon which the examinations are based.

The Agricultural School at Berlin has been injured by fire due to an explosion of gas. The loss is estimated at $15,000, in addition to the destruction of valuable collections.

Dr. Winthrop Ellsworth Stone has been elected president of Purdue University. He has been professor of chemistry in the institution since 1889, and vice-president since 1892.

It is said that Dr. George Edgar Vincent, professor of sociology at the University of Chicago, has been offered the presidency of Northwestern University.

Miss Laura D. Gill, A.B., A.M. (Smith College), has been appointed dean of Barnard College, Columbia University.

Dr. John E. Weeks has been appointed to the professorship of ophthalmology in the New York University and Bellevue Hospital Medical College made vacant by the death of Dr. Henry D. Noyes.

Austin M. Patterson, A.B., (Princeton), Ph.D. (John Hopkins), has been appointed instructor in chemistry in Centre College, Ky.

*THE ORIGIN, SCOPE AND SIGNIFICANCE OF BACTERIOLOGY.**

BACTERIOLOGY is a child of the 19th century. It is the offspring of chemistry and biology, enriched by physics with the gift of the achromatic microscope.

By the end of the first quarter of the century, natural philosophy, natural history and chemistry had almost wholly displaced the magic and alchemy of the Middle Ages and the Renaissance. Natural law was the explanation indicated by natural knowledge for natural phenomena, and in most cases a natural explanation of these phenomena was either discoverable or conceivable. The Copernican theory, as developed by Galileo, Kepler, Newton and their successors, accounted satisfactorily for the obvious structure and operation of the solar system. The researches of Vesalius and Harvey, and their successors, had made comprehensible the anatomy and physiology of the animal body. The earth, in response to the inquiries of Hutton and Lyell, was yielding up the record of its slow but sublime history, its very rocks bearing eloquent testimony to their natural origin. The lightning of heaven, the thunderbolt of Zeus, interrogated by our own Franklin, had confessed its affinity

* Address delivered by the president before the Society of American Bacteriologists, Baltimore, December 27, 1900.

to the humbler electricity of glass and amber. Everywhere the growth of natural knowledge revealed always more and more of natural law. Magic and mystery in the greater part of the macrocosm and microcosm were no more. Alchemy, the philosophers' stone and the transmutation of metals were gone forever. Yet even as late as 1835 there still remained one large group of familiar natural phenomena which was neither understood nor explained.

Fermentation, and especially alcoholic fermentation, had long excited the wonder of the ignorant, the curiosity of the wise. Fermentation was obviously the seat of active, spontaneous, self-regulated change. Its bubbling had given to it the name, which comes from the Latin *fervere*, to boil. Yeast was the constant accompaniment of the alcoholic fermentation, but exactly what yeast was no one knew. At best it seemed to be a consequence rather than a cause of fermentation, since it was more abundant at the end than at the beginning, more abundant in the later and less active stages than in the earlier and more active. Leeuwenhoeck indeed had examined yeast microscopically and found in it what seemed to be living cells, but his discovery appears to have occasioned no great surprise and to have been virtually forgotten after the lapse of a hundred and fifty years. The bubbling or boiling of the alcoholic fermentation suggested the action of acid on limestone, but as there was no limestone present and very little acid the suggestion explained nothing and was not very helpful. Chemistry had dealt with the alcoholic fermentation, and had come to the conclusion, based upon analyses and experiments, that it was a purely chemical process, in which sugar was decomposed wholly into alcohol and carbonic acid, the cause of the decomposition being the aggressive action of the oxygen of the air.

These were the days in which oxygen was much in fashion, for it had been only recently discovered by Priestley in 1774, and it was perhaps natural that Gay Lussac, reflecting upon the successful experiments by Appert in preserving foods by canning, should have concluded that it was the exclusion of the atmospheric oxygen from the tins which prevented fermentation of the fruit juices which they contained. He was confirmed in this opinion by his own experiment upon grape juice in the Torricellian vacuum, and his theory was, naturally enough, accepted and extended by his pupil Liebig. There were not wanting, however, objectors to this theory, nor experiments which seemed to disprove it, and it was never very satisfactory because it failed to account adequately, not only for the constant presence and growth of yeast—for which no provision was made in Gay Lussac's formula, —but also because of the total absence of oxygen in the most active stages of alcoholic fermentation as conducted in breweries, etc. For most persons, therefore, fermentation was still an unsolved problem when, in 1836, Schulze completely disproved the oxygen theory by showing that ordinary air, such as had been excluded in the experiments of Appert and Gay Lussac, was unable, even if admitted, to produce fermentation if it had first been caused to bubble slowly through concentrated sulphuric acid which, whatever else it might do, certainly could not deprive it of oxygen.

Putrefaction was another unsolved problem in nature, not only at the beginning of this century, but as late as 1835. It obviously resembled fermentation in some respects, and had often been classified with it, but yet it was also obviously different. Bubbling was not always an accompaniment of it, and the microscopes of the day, comparatively poor as they were, had revealed the almost constant presence in putrefactions of swarms of microscopic

forms of life roughly classified as 'animalcules.' These were either not present at all in the alcoholic fermentation or, if present, were few in number. Moreover, in this case also, the microscopic life seemed to be a consequence rather than a cause of putrefaction, inasmuch as it was most abundant, not at the beginning, but toward the end of the process. Meat kept in warm air or warm water soon 'spoiled,' though exactly how or why no one knew. Chemical changes were obvious and abundant, but of a totally different kind from those characterizing the fermentation of alcohol or vinegar.

Organic decomposition and decay, two of the most widespread and universal processes in nature, while occurring on every hand, were in the early part of our century either not understood or else incorrectly interpreted. The slow decay of timber and of teeth, the rapid decay of fruits and flowers, sometimes, it is true, suggested putrefactions, but quite as often went on almost insidiously and unobserved. Even after the first quarter of our century had gone by, slow decay was given a very large name, *eremacausis*, but yet was only imperfectly understood. The current explanation, such as it was, was in harmony with the few facts established by chemistry, viz., a theory of oxidation probably produced by the aggressive energy of free oxygen. Iron rusted readily enough; why should not wood and teeth and fruits 'rust' also in a somewhat different, but still essentially similar, way. This hypothesis seemed to be confirmed by the fact that canned fruits and foods were preserved so long as air was excluded from them, but spoiled soon after being exposed to the atmosphere. It was not observed, or if observed it was forgotten or believed to be immaterial, that meat and fish and fruits could be equally well preserved for an indefinite length of time by simple drying, although remaining constantly exposed in the dry condition to the aggressive action of the free oxygen of the air.

Nitrification, or the conversion of nitrogenous organic matter into mineral nitrates, was well known in the early part of our century as one of the most fundamental processes in nature and of prime importance in agriculture; manures, for example, being nitrified before they could become fit food for green plants. Precisely how this nitrification was effected, however, was not known, although it was suggested that free oxygen somehow oxidized organic nitrogen by a process similar to that in which it attacks iron. Obviously, this process went on best, if not exclusively, in the soil, for organic nitrogen elsewhere showed little or no tendency to unite with oxygen to form nitrates. The soil seemed to have some peculiar property of favoring this oxidation, but exactly what this property could be, unless it were a kind of platinum-sponge effect, was by no means clear even to the most eminent chemists and naturalists.

Natural 'heating' and 'sweating' were processes familiar enough to all observers of natural phenomena, but exactly what they meant no one in the early part of our century knew. Hay, imperfectly cured, heated and even rotted in the barn. Manure, collected in heaps, underwent a spontaneous and peculiar change by which it was altered or ripened, sometimes becoming intensely hot and giving off vapors which indicated profound and important chemical changes. Flax, in the course of the preparation of linen fiber, was made to undergo a peculiar maceration or change which must have suggested fermentation or decay and was known as rotting or 'retting.' Hides, in the peculiar and primitive processes preliminary to tanning, often underwent a similar change known as 'drenching.' Tobacco 'sweated,' and milk 'soured,' spontaneously. Cider 'turned' into vinegar, grape-juice into wine, and in various other domestic or indus-

trial processes advantage was taken of 'spontaneous' changes of highly peculiar and unexplained characteristics.

Contemporary spontaneous generation, in the first half of our century, was commonly accepted as a fact even by many scientific men, who held that it was the simplest explanation of the origin of the swarms of microscopic organisms observed in putrefying liquids or infusion. The belief in easy and constant spontaneous generation of living from lifeless matter is probably as old as the human race, and if we bear in mind the ignorance which was universal concerning the nature and complexity of even the simplest forms of life, and the complete lack of trustworthy evidence such as we have to-day against the theory of present-day abiogenesis, we can not wonder that this theory should have been so recently and so widely held. It is true that some of the most acute observers, such as Leeuwenhoek, had utterly refused to accept the theory, arguing that the total absence of abiogenesis in the higher forms of life made its occurrence in the lowest forms highly improbable, but we must admit that in these cases their conclusions were based rather upon instinct than scientific evidence. Granting, as we must, the theoretical possibility, and perhaps probability, of this process in the primordial origin of life upon our globe, we may well be slow to condemn those who leaned toward the theory of modern spontaneous generation as the most reasonable explanation of the myriad life of to-day in the under microscopic world. At the same time it can hardly be doubted that the belief in present-day spontaneous generation represented the last survival of such traces of belief in magic, alchemy, and the transmutation of metals, as the nineteenth century inherited from its predecessors.

In the early part of our century there was a group of natural phenomena of a different order, which, though painfully familiar, was equally puzzling and mysterious. Seemingly spontaneous in origin, always inexplicable, erratic and mysterious in transmission, often swift in operation and fatally destructive to human life, the mysterious phenomena known as *epidemics, plagues and pestilences* were among the most dreaded of all natural occurrences. Many indeed still spoke of them as 'visitations of the Almighty,' and treated them as if they were of superhuman origin, but Dr. William Farr, in preparing a classification of diseases for the purposes of the registration of vital statistics—made for the first time in history on a large scale in England in 1839—recorded epidemics, plagues and pestilences as strictly natural phenomena, though obscure, and while specifically denying any intention of considering them as fermentations, almost unconsciously acknowledged their affinity to fermentations by the name which he applied to them, and under which they have ever since been known, viz., the 'zymotic' or fermentative diseases. Dr. Farr gives no theory of their origin or causation and expressly declines to regard them as fermentations, partly, no doubt, because of the vehemence of Liebig, who was opposed to the idea, but also, we may believe, because the prevailing theory of the cause of fermentation was that it was due to the aggressive energy of free oxygen; and it would have been obviously too absurd to assert that free oxygen, the very breath of human life, is at the same time the cause of its worst diseases. In Germany, Henle arrived, largely from observation and *a priori* reasoning, at a conclusion essentially similar to Dr. Farr's, and, in America, Professor J. K. Mitchell, father of our distinguished physiologist and litterateur, Dr. Weir Mitchell, was urging, upon similar grounds, his able thesis 'On the Cryptogamous Origin of Malarious and Epidemic Fevers.'

To recapitulate.—While, in the first half of our century, the anatomy and physiology of the macrocosm and the microcosm, the heavens, the earth and man, were fairly well understood, there yet remained certain important natural phenomena either generally not understood at all or else, as we know, almost completely misinterpreted, namely, as follows:

1. Fermentation of every kind.
2. Putrefactions.
3. Organic decomposition and decay.
4. Nitrification.
5. The origin of microscopic life.
6. Zymotic diseases.

The end of the third decade of our century saw the beginning of a profound change in the accepted theories concerning all or nearly all of these phenomena. In 1836, Schulze proved that the oxygen theory of fermentation could not be correct. The next year Theodor Schwann confirmed his results by a different experiment, and by the improved achromatic microscope not only discovered, or rediscovered, the yeast plant, but also boldly asserted that the life and growth of this plant was the cause, and not the consequence, of the alcoholic fermentation. Thus, based on solid grounds, began the biological or germ theory of fermentation of which Schwann is entitled to be regarded as the founder, precisely as Pasteur some twenty years later became the founder of its direct descendant, the germ theory of disease. Confirmed or even slightly anticipated by Latour in his discovery of the living and vegetable character of yeast; supported by Helmholtz and Mitscherlich in his assertion that no alcoholic fermentation of sugar ordinarily occurs except as caused by yeast; and by Schroeder and Von Dusch in his claim that the cause of fermentation and putrefaction in boiled liquids is not air, but floating matters in the air; Schwann is entitled to be regarded as the immediate precursor of the bacteriologists and as having effectually paved the way for the first and greatest of all bacteriologists, Louis Pasteur.

Of Pasteur, the founder of our science, I shall only recall very briefly the principal facts of history:

Pasteur brought to the study of all the problems that I have enumerated—and I hardly need remind you that among them are some of the most elusive, some of the most profound, and some of the most intensely practical, problems in all the field of natural knowledge—a thorough working familiarity with physics and chemistry. Though not exactly a chemist, he was able to meet chemists upon their own ground. Though not exactly a microscopist, he was highly trained in physics and mineralogy, and thus quickly became a master of the microscope. Piqued by the fact that living ferments could do with his salts what he himself could not do, he began a careful study of ferments and fermentation, with the result that in a few short years he had completely confirmed and established the biological or germ theory of fermentation propounded by Schwann; had extended it so as to make it include putrefactions; had shown that organic decomposition and decay in nature are simply slow fermentations or putrefactions; had nearly, if not quite, overthrown the world-old theory of spontaneous generation; had studied the floating matter of the air, and actually found in it organized corpuscles, or germs, of molds and of infusorial or fermentation animalcules; had invented and introduced for the first time methods for the cultivation, and even for the pure cultivation, of living ferments which so much facilitated the investigation of microscopic life that we now rightly regard them as constituting the very basis and essence of bacteriology,—which thus becomes a kind of microscopic gardening or horticulture of the microscopic world; had also, by the use of these

novel methods, established not merely the fact that living ferments in general are the cause of fermentation in general, but, what was of equal or even greater importance, the existence of specific or characteristic ferments for particular fermentations, one, for example, producing the alcoholic fermentation, another the lactic, a third the butyric, a fourth the acetic, and so on. If to-day we have to modify this primitive simplicity of arrangement and refer rather to one group of ferments than to one species merely, nevertheless the idea of specific energies for specific ferments remains secure and underlies most of the practical work of bacteriology.

Finally, through his work on industrial micro-biology, on the yeasts and the ferments of milk, vinegar, etc., Pasteur was led not only to consider the applications of bacteriology to the useful arts, but also to study the ailments of fermented drinks and the causes of their deterioration or 'disease,' with the result that in discovering and proclaiming the sources of the diseases of wine and beer as residing in specific noxious ferments or germs carelessly or unwittingly introduced, he became, almost unconsciously, not merely the apostle and defender of the biological or germ theory of fermentation, but also the principal contemporary exponent of the biological or germ theory of disease; a theory which had long been a dream of pathologists and now suddenly rose into scientific as well as popular favor.

Such was the origin of bacteriology, and such were some of the early achievements of its great founder. Stimulated by the work of Pasteur, a host of eager and enthusiastic workers threw themselves with intense zeal into the study of the micro-organisms which constitute the field of microbiology. Time has proved beyond all peradventure that the foundations laid by Pasteur were laid solidly and securely. The *fermentations* are in fact what he and his precursor Schwann believed them to be, viz., chemical changes produced by living ferments, which, taken together, we may call microbes. *Putrefactions* are, as Pasteur believed them to be, essentially anaërobic fermentations. *Present-day spontaneous generation* is, as Pasteur claimed, a myth—the last survivor of the notions of the alchemists. *Organic decomposition and decay* in nature have been found to be simply slow fermentations and putrefactions. *Nitrification*, or the natural mineralization of organic matter, is essentially an oxidizing fermentation, as is also, for example, the making of vinegar, from alcoholic cider. The *infectious or zymotic diseases* are either harmful fermentations, or the results of such fermentations, occurring not merely in wine, beer and vinegar, but, as Pasteur himself showed in the case of the silk-worm, in or upon the animal—and, we may now add, the plant—body.

A careful review of the subject from our present relatively advanced position shows that the really distinguishing characteristic of bacteriology is not merely its subject matter but its methods, not so much the peculiar organisms with which it deals—interesting and important though these are—as the peculiar means it has devised and employed for studying these organisms. In this respect bacteriology differs widely from any other science bearing the name of a particular class of plants or animals. Sciences such as mammalogy, ornithology, entomology, dendrology, pteridology, bryology, algology, mycology, lichenology and the like are chiefly, though not exclusively, characterized by the peculiarities of the special forms of life with which they deal, the methods by which they are pursued being largely common to all or at least in no great degree either peculiar or extraordinary. In bacteriology, on the contrary, owing, no doubt, to the small size and ap-

parent similarity of the organisms concerned, the ordinary methods of study and of classification are quite insufficient, so that new and highly peculiar methods have been devised and employed. Bacteriology does not depend, as ornithology and entomology chiefly do, on the external and internal anatomical features of individuals, but only to a small extent on these, and chiefly on the behavior of flocks, swarms, groups or masses of individuals, and upon these not in a state of nature but artifically massed or cultivated. Bacteriology finds its closest analogy not in such sciences as ornithology or bryology—the science of birds or the science of mosses—but in such sciences as breeding, gardening or agriculture. Possibly bee-keeping (apiculture) offers an analogy as useful as any. In apiculture bees are dealt with not so much as individuals, as communities or 'colonies,' and the swarms are bred, cared for or cultivated largely as masses and by methods highly peculiar. Bacteriology is a kind of microscopic horticulture or apiculture, and its methods, introduced in the first instance by Pasteur for yeasts and twenty years later vastly improved by Koch, are applicable to many bacteria and yeasts—though certainly not equally to all—and also to some molds and other fungi, and, to some extent, to certain algæ and protozoa. If we define as micro-organisms or microbes all organisms invisible or barely visible to the naked eye, we may conveniently describe their study as micro-biology. *Bacteriology* then *is a sub-division of micro-biology* and is conveniently defined as *the science of the culturable micro-organisms.*

Enough has perhaps been said already, in dealing with the origin of bacteriology, to indicate sufficiently the scope and significance of the culturable micro-organisms in nature. But when we reflect upon the simple fact that without their activity the habitable world and the sea would become one vast charnel-house, because there would be no adequate agency for mineralizing dead matter, we begin to realize the enormous importance of the part which they play in the economy of nature. We have only to think of their helpful and wholesome unseen activity in removing from our view the dead animal bodies which would otherwise cover the earth, the dead leafage of the autumn, the worn-out trunks of trees, and the waste matters of human and animal life, in order to appreciate in some measure their fundamental importance in nature. When to this we and their tendency to cause the destruction of valuable organic matters, such as food and timber; their function in producing those fermentations, putrefactions and poisonings of the human body which we know as epidemics, plagues, pestilences, infectious diseases, suppurating wounds, gangrene and the like; when, furthermore, we consider their causative participation in such universal, familiar and important processes as bread-making, brewing, vinegar-making, the fermentations of milk and its products, butter-making, cheese-making, lactic acid manufacture, tanning and nitrification, we are in a position to understand something of the scope and significance of the culturable micro-organisms, and therefore of bacteriology, from a practical point of view. And while we cannot forget that our science had its most fruitful beginnings in pure science at the hands of a physiologist, Schwann, and a natural philosopher, Pasteur, we must allow that its highest cultivation and its richest fruits have come from the labors of medical men. The names of Lister, Burdon-Sanderson, Koch, Behring, Roux and many others are the most famous, and their wonderful researches, with the brilliant practical results of their labors for human welfare and progress, by far the most splendid achievements of bacteriology in the last

quarter of our century,—the post-Pasteur period.

But in the last analysis it is the higher significance of bacteriology which must always be regarded as its most important characteristic. By virtue of the discoveries upon which it was founded, to which it has led and upon which to-day it rests illustrious and secure, mankind has been enabled for the first time to arrive at an adequate comprehension and understanding of the microscopic world and of many important and familiar natural phenomena hitherto either not understood or misinterpreted. The origin of bacteriology is interesting and instructive; its scope is broad and comprehensive; but these matters are of only moderate consequence as compared with its philosophical significance. At the beginning of our century, in absolute ignorance of bacteriology and its wonderful teachings, man gazed with wonder or indifference on some of the most familiar, yet most mysterious, of natural phenomena. Organic matters almost everywhere slowly 'decayed' and disappeared; sweet and sugary fruit juices 'turned' rapidly and 'spontaneously' into pungent or acid liquors; slow and innocuous 'decomposition' often gave place to foul 'putrefaction' and rapid 'decay' or destructive 'rots'; manure applied to land, even to land lying fallow, soon vanished altogether; 'epidemics, "plagues' and 'pestilences' swept over the earth, and man could neither understand, nor explain, nor intelligently fight them; the microscopic world quivered with forms of life which seemed to be born in a day and to disappear like dew. The heavens had long since revealed the glory of God, and the firmament,—thanks to the interpretations of Copernicus, Galileo and Newton,—had abundantly shown his handiwork. But the microscopic world still sat in the shadow of darkness, awaiting the disclosure of its meaning. At last, in the fulness of time and largely through the achromatic objective, a great light shone upon and from the under world. The mysteries of fermentation, putrefaction, organic decomposition, decay and the mineralization of organic matters were reduced to their lowest terms and brought into line with other problems of biology. Epidemics, plagues and pestilences were proved to be merely the ravages of micro-parasites; the life of the under world was scrutinized, classified and studied, and has been found to follow in general the same natural laws as that of the upper world. Bacteriology has given to us a comprehension of the under world similar to that which astronomy and astro-physics have given us of the heavens; the widely-accepted theory of present-day spontaneous generation has been proved to be a myth, and with the fading out of this ancient view of nature the last traces of medieval ideas of magic, alchemy and easy transmutation of the elements have disappeared from science.

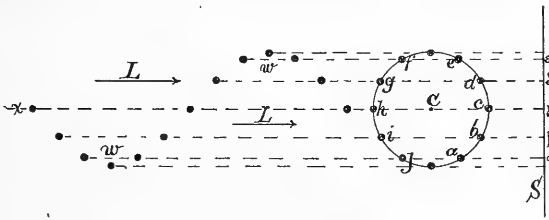
CERTAIN STROBOSCOPIC PHENOMENA IN THE END-ON PROJECTION OF A SINGLE WAVE.

IN projecting a plane polarized wave machine wave, *ww*, with a lens on a distant screen, *S*, one observes when the wave is in vigorous motion that the balls appear on the screen as stationary objects, symmetrically disposed with reference to the axis of advance of the wave, or the direction of incident light, *LL*, and at distances apart corresponding to equal phase-differences. Clearly the same effect must be produced in rotating the circle of reference, *C*, if provided with balls, *a*, *b*, *c*—at equal angular distances apart on the circumference. As certain parts of this phenomenon are peculiar, I constructed a disk like *C* by soldering bright rods at right angles to its surface at *a*, *b*, *c*—with an axle at *C*.

When the disk revolves, however rapidly, in the beam of sunlight parallel to its surface as stated, the eye regarding the *inner* surfaces of the rods *a*, *b*, *c*, *d*, *e*, sees the usual sheen of light intersected with intensely black shadow bands due to *f*, *g*, *h*, *i*, *j*, projected in the positions *a*, *b*, *c*, *d*, *e*. The experiment is specially striking in a dark room. This phenomenon is easily explained, for the points *a*, *b*, *c*—are nodal points, as it were, or loci of perpetual eclipse.

The second phenomenon is even more striking: if the light after passing the revolving disk parallel to its face (which therefore is seen as a mere line) is caught on a screen, either close at hand without a lens, or at long range by lens projection, the loci α, β, γ, δ, ϵ, are again stationary, appearing however *bright* on a dark ground. Judged merely by the eye, the effect is just as if the rods where they cross in double thickness were perfectly transparent. It would take considerable acumen to predict this kinematic result.



Without entering into details, I may point out in explanation that every part of the area of projection, *S*, is swept by the shadow of each rod twice per rotation. The result must be perceptible and at first sight uniform darkening of the field. But whereas throughout the whole semicircle, *f*, *g*, *h*,—and also *between* the points *a*, *b*, *c*,—light has been removed backwards (*i. e.*, from the screen) by reflection, none has been removed at the points *a*, *b*, *c*; for these appear as black lines in the sheen of revolving rods. Hence more light must get through along the lines *fe*, *gd*, *hc*, than in the same direction between these lines.

THE INTERNATIONAL GEODETIC ASSOCIATION.

THE sessions of the Thirteenth General Conference of the International Geodetic Association were held at Paris, France, between the 25th of September and the 6th of October, 1900.

The following countries were represented at the Conference: Germany (8), Austria (2), Denmark (1), Spain (1), United States (1), Great Britain (1), Hungary (1), Italy (3), Japan (1), Mexico (2), Norway (1), Holland (3), Roumania (2), Russia (1), Sweden (1), Switzerland (1), France (8), the number following the name of each country indicating the number of delegates sent from the country. Belgium, Greece and Portugal were not represented.

At the opening session of the Conference the French Minister of Public Instruction presided, and welcomed the delegates in the name of the French Government. The sessions were held in the new Sorbonne, and a great many interesting reports were read. From these reports the following details have been extracted:

M. Schumann has undertaken a new computation of all the great arcs already measured, in order to deduce the elements of the terrestrial ellipsoid.

By relative gravity measures, M. Schumann has connected Königsberg, Guldenstein, Copenhagen and Christiania with Potsdam.

M. Borrass has connected Bucharest with Potsdam; M. Nagaoka will soon connect Tokio with Potsdam; and M. Putnam has recently connected Washington with London, Greenwich, Kew, Potsdam and Paris.

The funds of the association will be used to effect other connections of the principal gravity stations of Europe.

M. Helmert continues to keep up complete statistics of relative gravity stations. The actual number of these stations is now 1,450, of which 83 are connection stations. The results are very numerous, and the exact connection of the principal stations is an accomplished fact. M. Helmert hopes to be able, in 1901, to give a comprehensive discussion of all the results so far obtained.

A report was made upon the observations already made at international latitude stations, and the provisional calculations of the observations so far made have given satisfactory results.

General Bassot suggested the desirability of making similar observations on a parallel in the Southern Hemisphere.

The labors of Albrecht and Chandler have made great progress in developing the theoretical question of the variation of latitude. The first, from observations at 13 stations in Europe and America, from 1890 to 1897, has shown that the pole of rotation of the earth has described in that space of time an irregular spiral about a mean position, with a maximum elongation of $0''.30$. The second, after a profound discussion of observations made between 1825 and 1893, represents this displacement by an expression of two terms, periodic functions of time. The period of the first oscillation covers 429 mean days, that of the second 365. These terms vary, respectively, from $0''.085$ to $0''.185$ and from $0''.115$ to $0''.135$. The mechanical causes of the displacement of the terrestrial axis of rotation are still far from being known.

A resolution was passed requesting Professor Gore to prepare a new edition of his *Bibliography of Geodesy*, issued by the Coast and Geodetic Survey in 1889.

A special report on triangulation was made by General Ferrero, and on base lines by General Bassot.

The French Geographic Service has undertaken a revision of all the French triangulation, with the aid of the instruments and methods of high precision used in the New Meridian of France; and work is actually in progress on the parallel of Paris.

In Italy the geodetic junction of Malta and Sicily has been made.

Roumania submitted her first report of geodetic work. The arc of the parallel already measured between the Atlantic Ocean and the Danube has been extended across Roumania to the Black Sea, and the meridional arc measure by Struve between the Arctic Ocean and the Danube has been extended entirely across the country.

In Russia the recomputation of all trigonometric points upon the same spheroid has been undertaken. A determination of the terrestrial elements from Russian arcs alone shows that the elements of Bessel conform more nearly to the curvature within the boundaries of Russia than those of Clarke.

Two proposed operations were submitted to the Conference:

The Observatory at Nice will undertake experiments to determine the velocity of sound and light, using the distance between Mt. Mounier, near Nice, and Mt. Rotondo, in Corsica. This distance will be redetermined with modern precision by the French and Italian geodesists.

The difference of longitude, Paris-Greenwich, will again be determined according

to an elaborate program. One determination will be made in October, 1901, and another in March, 1902, so that the first results can be discussed before undertaking the second set of observations. Two pairs of observers, using four instruments, as nearly similar as possible, will be employed. At each station the French and English observers will frequently exchange their instruments. The pairs of instruments and observers will be exchanged twice during each determination. The method employed will be submitted to the examination and approval of the Central Bureau of the Association.

In this connection M. Albrecht called attention to the advantage of using the registering micrometer of the Repsold system, which eliminates the personal equation of observers.

Mr. Foerster spoke of errors resulting from the instability of the optical axes of instruments, caused by the movement of the objectives in their mounting.

General Bassot emphasized the necessity of watching attentively the nature and constancy of the electric communication, whose variability may explain the marked differences.

M. Cornu exhibited and explained an apparatus to determine the zenith distance of a star culminating near the zenith. On motion of M. Hirsch the Association resolved that a similar apparatus should be constructed and studied in one of the great observatories, and that M. Cornu, continuing his useful studies, should realize a portable zenitho-nadiral apparatus for use in temporary observatories, permitting numerous and easy determinations of latitude at all the points of a geodetic net.

Upon the invitation of the Association, M. Guillaume, of the International Bureau of Weights and Measures, presented a very interesting communication concerning nickel-steel. He remarked in 1896 that nickel-steel, with 30 per cent. nickel, had an expansion sensibly less than platinum, and since then has conducted most interesting studies concerning these alloys. He dwelt upon their singular magnetic, thermometric and mechanical properties, and stated that a certain alloy with 35 per cent. to 36 per cent. nickel possesses an expansion ten times less than that of platinum and twenty times less than that of brass. He then passed to the uses of the alloy for geodetic purposes. He considers it impracticable to use the alloy in the construction of standards of the first order, where perfect stability and invariable dimensions within the limits of precision measures are demanded for long periods of time, on account of certain changes which have been observed as a function of time. In geodesy the question presents a different aspect, and it suffices in practise that the length varies very little, say a millionth part in a year, and that the change should be very regular. The small coefficient of expansion, the malleability, the feeble oxidation, and the homogeneous character of these alloys all increase their usefulness in the construction or use of geodetic instruments.

The applications of nickel-steel have passed the experimental stage and entered the practical field in the two methods of measuring bases actually in use, viz., those of rigid bars and wires.

The problem of constructing a base bar has been solved in a very satisfactory manner in the one actually being constructed for the Geographic Service of the French Army, from the plans of MM. Benoit and Guillaume. The bar, which is four meters long, has a section in the form of an H inscribed in a square of 40 millimeters. It is enclosed in a case, made of an alloy of aluminum, with openings for necessary observations. It rests in its case on two normal points of minimum flexure. It weighs 50 kilos, case included.

Nickel-steel wires have been made and furnished to the Geographic Service of the French army, to the Swedish-Russian Expedition to Spitzbergen and to the Geodetic Service of Cape Colony, for experimental use.

Work in Spitzbergen is in progress under the extremely difficult climatic conditions usually found in this region. The missions sent out by the two Governments were engaged in field work from the last of June to the beginning of September. They are now in winter quarters, isolated from the rest of the world during nine months, engaged in making astronomical and meteorological observations and in studying gravity, refraction, etc.

Sir David Gill addressed the Association on the motion of Professor Darwin, the delegate from Great Britain. He announced that since the publication of the first volume of the Geodetic Survey of South Africa, two extensions of the Geodetic Survey have been undertaken there. The first was required for the purpose of delimiting the boundary of British Bechuanaland and German Southwest Africa; with the cordial cooperation of both governments concerned, it was arranged to carry out this work as far as latitude 22° S. with the accuracy of a geodetic operation.

Connection was made with previous work, and the combination of these observations secures the measurement of a latitude arc along the 20th meridan from Cape Agulhas, (the southernmost point of Africa), to latitude 22° S.—an arc of nearly 13°.

The second operation is the more important of the two, and provides for the extension of an arc along the 30th meridan of E. longitude, from the southern border of Rhodesia (22° S.), to the southern end of Lake Tanganyika. The work owes its inception to the enlightened policy of the Chartered Company, which has accepted the results of all experience and has determined to base its surveys of the country on a framework of the most accurate possible triangulation. The work has been in progress for some years and a chain of triangulation has been carried along the 30th meridian from Gwelo (lat. 19½° S.) to the Zambesi.

Sir David Gill plans an extension of this work to Alexandria, Egypt, with the cooperation of Germany and Belgium through their African possessions, and of the Egyptian Government, and sees no special difficulties in the way of accomplishing the measurement of this great meridional arc, covering 66° of latitude.

Splendid as is the scientific prospect which the realization of these projects would present, its importance is further enhanced by the consideration that by the execution of a triangulation around the Levant to join Struve's great arc of the meridian (which extends from the North Cape, in Norway, along the 30th meridian to the southern limit of Russian territory), an arc having an amplitude of 104° would be completed.

A resolution was adopted expressing appreciation and approval of the project proposed by Sir David Gill.

The new measure of the Equatorial Arc of the meridian, known as the Peruvian Arc, undertaken by the Geographic Service of the French Army, was discussed by the Association with great interest. Captains Maurain and Lacombe, of this service, spent five months in South America during 1899, and finished the reconnoissance, during this time, of an arc of 6°, extending the old arc 1° on the north and 2° on the south. The scheme includes base lines, azimuth stations, astronomical observations, leveling, gravity and magnetic observations, topographical work and geological investigations.

The French Minister of Public Instruction referred the report of MM. Maurain and Lacombe to the French Academy of Sciences

for a statement whether the interests of science required this long extension of the arc, and the Academy has replied, through M. Poincaré, that the arc should be extended to 6°, and that the Academy should exercise a scientific control of the work through a permanent commission, but that the actual work on the ground should be confided to the Geographic Service of the French Army.

The sentiment of the Association was in favor of the prompt execution of this work. It was stated that two officers would shortly leave for South America to finish all preliminary preparations, and that three other officers and their staff would probably start about the last of April, 1901, to take up the field work. A French astronomer is already in charge of the observatory at Quito, under appointment from the Government of Ecuador.

During the discussion of the project for a great meridional arc in Africa, proposed by Sir David Gill, the Astronomer Royal at the Cape of Good Hope, I had occasion to make the following remarks, in response to the request of Professor Darwin for some statement from the delegate of the United States in reference to the suggestion offered by General Bassot, one of the French delegates, that in America there was an opportunity of measuring an arc of the meridian from Cape Horn on the south to the Arctic Ocean on the north :

"In response to the request of M. Darwin, I have the honor of expressing my appreciation and admiration of the grand scheme of triangulation proposed by Professor Gill, Director of the Observatory of the Cape, and take pleasure in stating that the motion for its endorsement by the International Geodetic Association will receive my earnest support. I will present the plan to my government and feel confident that it will receive all possible support from the geodesists of my country.

"In reference to the suggestion of General Bassot that a great meridional arc might be measured in America, I have to state that the United States is now engaged in measuring an arc along the 98th meridian west of Greenwich, which will extend entirely across the country and cover 23° of latitude.

"The details of the condition of this work at this time will be found in my report to the Association.

"This arc can be extended south 9° of latitude by Mexico, and north by Canada to the limit of ice and snow in the Arctic regions, an unknown distance. I do not think that my Government is prepared to undertake any extension of the above scheme at present."

After discussing Sir David Gill's scheme, the Association indicated its approval by a unanimous vote.

When the report on the new measurement of the Equatorial Arc (known as the Arc of Peru), was before the Association, I took occasion to make the following statement :

"The delegate on the part of the United States desires to express, in the most positive manner, admiration and appreciation of the work already accomplished by the French geodesists, as shown in their report on the reconnoissance of the Arc of the Meridian of Quito, and to extend to them the most cordial congratulations.

"Feeling the deepest interest in the prosecution of the work and in its successful completion, he trusts that no serious obstacle will cause delay.

"Its ultimate completion is assured, now that it has been undertaken by those who will make any necessary sacrifice to add this additional glory to the illustrious position already attained by French geodesists.

"If assistance of any kind is needed to complete the work, he hopes that his country will be given preference in doing all in its power to supply whatever is demanded by the exigencies of the case."

ISAAC WINSTON.

U. S. COAST AND GEODETIC SURVEY.

THE ALBANY MEETING OF THE GEOLOGICAL SOCIETY OF AMERICA.

II.

Stereographic Projection in Map-Construction: SAMUEL L. PENFIELD, New Haven, Conn.

By means of lantern slides and diagrams, Professor Penfield illustrated the methods of projecting maps of the various parts or countries of the globe upon the plane of its equator or of any other great circle. The methods are those employed by crystallographers for the projection of the polar points

of crystals and possess many advantages over the Mercator's projection or the ordinary maps which are practically pictures without definite mathematical proportions. Professor Penfield has constructed a series of scales which correspond to the projections of arcs by the stereographic method, and which enable one to measure distances between points of the earth whose latitudes and longitudes are known. Great accuracy can be obtained even when the projections are made on a circle whose diameter is less than six inches. The paper appears in the January number of the *American Journal of Science* and should be read by all teachers of geography.

The Paleozoic Limestones of the Kittatinny Valley, N. J.: HENRY B. KÜMMEL, Trenton, N. J., and STUART WELLER, Chicago, Ill.

The Paleozoic limestones of the Kittatinny Valley are divisible into the Kittatinny formation below and the Trenton above. The former is a magnesian limestone, probably 3,000 feet thick, and ranges from lower Cambrian into the Calciferous, with no structural or marked lithological differences. The Trenton limestone, about 135 feet thick, carries in its lower beds the Black River fauna, making it the equivalent of the lower Trenton of New York. A conspicuous and widespread basal conglomerate at the bottom of the Trenton rests upon the eroded surface of the Kittatinny formation. The lithological and faunal characteristics of the formations were described and their structural relations shown. The extent and importance of the basal conglomerate were outlined.

In discussion, M. R. Campbell inquired if the Trenton conglomerate changed in thickness from northwest to southeast. Mr. Kümmel replied that it did not, generally, although there was some variation in that the conglomerate appears to have been formed at the foot of cliffs. Mr. Campbell stated that he had noted somewhat similar relations in Virginia, but that the conglomerate appeared on the northwest sides of the valleys and not on the southeast. He explained it as due to an interval of erosion and to the direction of the currents. N. S. Shaler cited parallel conditions in Kentucky and remarked the tendency of the limestones to thicken toward the northwest, not only in the Trenton but in the Lower Carboniferous and in the Coal Measures as well. He explained this by an Appalachian island to the eastward. J. M. Clarke mentioned a basal conglomerate in the Trenton near Albany, with fossiliferous pebbles containing a different fauna from the cement. J. F. Kemp cited a conglomerate of boulders of gneiss enclosed in a limestone cement in the thin Trenton outlier, within the southern Adirondack crystallines, at Wellstown, N. Y. The boulders are several inches in diameter, are similar to the neighboring gneisses and have apparently been dropped by floating ice. T. C. Hopkins remarked the Trenton conglomerate of the Nittany Valley, Penn., and its likeness to that of New Jersey.

The Niagara Group along the Western Side of the Cincinnati Anticline: AUG. F. FOERSTE, Dayton, Ohio.

The paper described the lithology, paleontology and physiography of the Niagara Group, with special reference to Middle Tennessee. It was the continuation of an investigation which had been partially described to the Society at a previous meeting, and which had for its object the determination of the time of upheaval and the structural relations of the Cincinnati uplift. Mr. Foerste traced the several component strata from north to south on both sides of the great fold, from Ohio into Central Tennessee, and especially emphasized the excellent section presented at Newsome, Tenn. He

had observed that the Clinton fossils of New York occur at higher and higher horizons as one goes westward, and by this observation he was led to correct some previous errors of correlation. He placed the crest of the fold farther west than is ordinarily done, and made the upheaval later than the close of the Ordovician and earlier than the Hamilton, whose shale goes unconformably over the strata on the flanks.

At the conclusion of the paper the Society adjourned for lunch. On reassembling the program was continued as follows:

The Knoydart Formation in Nova Scotia—a bit of the 'Old Red Sandstone' of Europe: H. M. AMI, Ottawa.

The presence of such genera as *Pteraspis, Pterygotus Onchus*, etc., in the red marls, shales and calcareous breccias (?) of McArras Brook in Antigonish and Pictou counties, Nova Scotia, indicates the base of the 'Old Red Sandstone' of Great Britain. The paper discussed the relations, paleontological and stratigraphical, of this important formation in the sequence of Devonian strata in eastern Canada. The result of observations made by Mr. Hugh Plebden, of the Canadian Geological Survey, as published on this subject, together with important notes by Mr. A. Smith Woodward and Dr. Henry Woodward, of the British Museum, was embodied in the paper.

The names applied by Mr. Ami to the several formations of this section are the following:

The Silurian of the Arisaig Coast of Nova Scotia is divisible into at least four distinct geological formations, and includes:

1. *The Stoneham formation*, consisting for the most part of dark red and fine grained shales and mudstones, holding a conspicuous, lamellibranchiate fauna, of which *Grammysia Acadica*, Billings is a well-known species, together with a number of interstratified, more or less thin, calcareous bands, holding brachiopods, gastropods, trilobites and ostracods in abundance.

2. *The Moydart formation* consisting of more or less heavy bedded, light greenish-gray and rusty weathering, calcareous strata, in which the author's 'Red Stratum' occurs—holding brachiopods, cephalopods, crinoids and gasteropods.

3. *The McAdam formation* consisting for the most part of impure, black, carbonaceous, at times splintery shale, holding a lamellibranchiate fauna, graptolites, etc.

4. *The Arisaig formation* including buff-weathering, fine grained and compact mudstones and shales, holding corals, chiefly Streptoplasma and brachiopods, gastropods and trilobites.

5. *Knoydart formation* red shales and sandstones and calcareous bands, holding pteraspidian and ostracoderm fishes and crustaceans, referable to the Cornstone or lower Old Red Sandstone of Great Britain. It immediately overlies the Silurian strata at Arisaig, but no actual contact has been observed.

H. S. Williams inquired about the igneous rocks at the top and in further detail regarding the Knoydart formation. Mr. Ami replied that igneous rocks were present. The strata had been mapped as upper Devonian, but that they really were lower Devonian and possessed a pronounced Silurian facies. The whole series is much more closely related to the British fauna than to that of Anticosti.

A Depositional Measure of Unconformity: CHARLES R. KEYES, Des Moines, Iowa. The paper was read by W. B. SCOTT.

The great unconformity at the base of the Coal Measures in the upper Mississippi Valley was briefly characterized in its various aspects. The enormous thickness of Coal Measures in Arkansas and Indian Territory finds adequate explanation in the ancient geographic development. The recent

results of correlation of the north and south regions were summed up. Twenty thousand feet of the Arkansas Coal Measures are found to have been deposited during the period represented by the great stratigraphic break in the north. No discussion.

Marine and Fresh-water Beaches in Ontario. A. P. COLEMAN, Toronto, Canada.

Marine deposits, often rich in shells and other fossils, are widely distributed east of Brockville and Smith's Falls, in the valleys of the Ottawa and St. Lawrence. They occur at higher levels toward the northeast and east than towards Brockville; they include trees and other forms indicating a climate like that of to-day, and are all evidently postglacial. The shells occur in clay, sand and also coarse gravel.

High beaches, such as the Iroquois, Warren, etc., contain only fresh-water shells, if any. Still higher beaches, such as those reaching 1,400 to 1,600 feet above sea level in the highlands between Georgian Bay and Lake Huron, and the beaches found above 1,400 feet between Lake Superior and Missanabie, and at the same level on the Hudson Bay watershed northwest of Sudbury, have not yet been found to contain shells, although if marine there must have been complete and widely opened connection with the sea. The wide gravel terraces on the watershed mentioned contain numerous and large, kettle-shaped, lake basins, sometimes without outlets, suggesting that they were formed by the burial of large blocks of ice at the border of the Labradorian ice sheet, and hence in ice dammed waters.

In discussion Robert Bell explained the presence of fresh-water shells amid marine conditions because of the forcing back of salt water by an inflowing stream of fresh. On the north side of Lake Superior he cited the occurrence of marine shells up to 500 feet, but their absence in the high gravels. He argued against the existence of ice dams in the past. G. K. Gilbert described the phenomena along the St. Lawrence east of Lake Ontario. He cited the occurrence of marine shells as far as Ogdensburg. C. H. Hitchcock referred to the sea-shore plants that are found around Lake Superior, apparently left by the withdrawal of the salt water. He also suggested that the basin of Lake Ontario might be due to the removal of limestone in solution. F. B. Taylor discussed the shell-beds, beaches and ice-dams. H. P. Cushing instanced the high gravels and general physiography of the Adirondacks as bearing on the questions. The Adirondacks embrace the high mountains, the western peneplain plateau and the depressed lakes. Kettle-holes occur on the north side but not on the south. Ice dams are proved by the kames left by subglacial streams which flowed against the slope of the country.

The Geology of Rigaud Mountain, Province of Quebec, Canada: OSMOND EDGAR LEROY, Montreal, Can. Introduced by F. D. ADAMS.

The chief topographic feature of the Paleozoic plain of Central Canada is a series of hills, which occur in the district about Montreal. These are of igneous origin, and follow a line of disturbance which is almost at right angles to the trend of the Notre Dame Mountains. Rigaud is the most western of the series. It consists of an area of hornblende syenite, which is pierced on its northern flank by a quartz syenite porphyry. The field relations of all the hills with the exception of Rigaud, show them to be of post-Silurian age. In the case of the latter, the contact with the Paleozoic is wholly concealed by drift. The object of the research was to ascertain if a genetic connection could be established between Rigaud and the other hills to the east.

Investigation shows that it is probably

not so connected, but a definite conclusion cannot be reached until a more extended study is made of the rest of the range.

In discussion, F. D. Adams commented on the interest attaching to this mountain both in its petrographic and stratigraphic relations. Mention was made by others of the benches of boulders which lie on the side of Rigaud. It was brought out that they are coarse cobbles, entirely unglaciated and all of local origin. They are known as the Devil's Garden and are at least thirty feet deep, but have no fine material between them. N. S. Shaler, therefore, remarked that they could not be beach-deposits, else they would be packed with sand. The interpretation of the boulders is an interesting point in post-glacial geology, but it still remains to be solved. J. F. Kemp remarked the similarity of the syenite to that of the Adirondacks, especially as described by H. P. Cushing in an earlier paper.

At the conclusion of Mr. Leroy's paper the session adjourned.

In the evening the Society was most hospitably entertained by Dr. and Mrs. F. J. H. Merrill and had the opportunity of meeting many Albany people.

On reconvening on Saturday morning the most important executive business was the adoption of a resolution recommended by the Council, which read as follows :

Resolved, That recognizing the great, historical, scientific and economic value of the collections of the State Museum in Albany, representing the geology and paleontology of the State of New York, the Geological Society of America expresses the earnest hope that an ample and fireproof building may be provided for the display of the priceless collections, where they may be accessible to students interested in the progress of science and the economic development of the State.

The Society then listened to the Presidential address of Dr. George M. Dawson, who took for his subject 'The Geological Record of the Rocky Mountain Region.' The paper was illustrated by maps and by comparative stratigraphic sections both east and west of the Canadian Rockies. It dealt especially with Canada and will be probably printed in full in a later number of SCIENCE.

The following paper was read in abstract by G. P. Merrill.

Weathering of the Granitic Rocks of Georgia: THOMAS L. WATSON, Atlanta, Ga.

The paper embraces the results of a detailed field and laboratory study of the principal exposures of the granitic rocks in Georgia. On structural and textural grounds, the rocks were divided into and discussed under (*a*) the true granites with even-grain texture ; (*b*) porphyritic granites; and (*c*) granite-gneisses. Each type, as here distinguished, is represented by a number of localities in somewhat widely separated parts of the State. In mineral and chemical composition, the rocks are closely similar, and all carry biotite as the chief accessory.

The physical conditions of the fresh rock and of its accompanying, decayed product as studied in the field were carefully stated, and each was described petrographically, the description being followed by a discussion, based on chemical analyses, of the changes incident upon weathering.

In taking up the changes manifested in the weathering of the rocks, as shown in the analyses, calculated amounts of each constitutent lost and saved were separately made on three assumptions, namely, that the Fe_2O_3, the Al_2O_3 and the $Fe_2O_3+Al_2O_3$ have undergone no loss. The results were then compared. With the exception of the total loss for the entire rock, the results proved to be closely similar for the three assumptions.

The Peneplain of Brittany: W. M. DAVIS, Cambridge, Mass.

The paper consisted of an exhibition of lantern slides illustrating the peneplain of Brittany, and of its detached portions in Jersey and Belle Isle, as well as of certain valleys by which the peneplain has been dissected since its elevation; and of comments in which the speaker argued that the plain was not one of marine denudation, but was subaërial.

The paper led to a quite extended discussion of the criteria for plains of marine origin, chiefly emphasized by N. S. Shaler and H. M. Ami, and of those of subaërial character, as developed by C. D. Walcott and G. K. Gilbert.

An Excursion to Colorado Canyon: W. M. DAVIS, Cambridge, Mass.

Observations made in the canyon of the Colorado and over the plateaus on the north and south, during a three weeks' trip in June, 1900, add the occurrence of certain landslides and migrating divides to the evidence already stated by Dutton in favor of two cycles of erosion in the development of the Grand Canyon district; the broad denudation of the plateaus having been accomplished in the first cycle, and the incision of the narrow canyons in the second. The faults by which the plateaus are divided are regarded as for the most part of greater antiquity than the canyon cycle; the antecedent origin of all the branch streams of the Colorado in this district is questioned; and the high level floor of the Toroweap valley is explained otherwise than by the failure of its former water supply through a change from a humid to an arid climate.

G. K. Gilbert corroborated the probability of the speaker's views from the evidence of neighboring systems of drainage, and C. D. Walcott spoke in the same vein.

Fossiliferous Layers in the Calciferous of Dutchess County, N. Y.: W. B. DWIGHT, Poughkeepsie, N. Y.

The paper described some recent discoveries of a Calciferous fauna, somewhat related to the Fort Cassin fauna of Vermont. It seems to identify the Calciferous for the first time so far south. It contains 24 species, of which 9 are trilobites.

C. D. Walcott remarked its resemblance to the fauna at Phillipsburg, Vt., and to another at Eureka, Nev.

Glacial Phenomena in Eastern Ontario: F. B. TAYLOR.

The speaker described the results of his observations of the moraines and other glacial phenomena in the portion of Ontario lying between Georgian Bay and Lake Ontario. At least four moraines can be identified which he endeavored to trace out to a connection with those further south. He also described an old river channel near Guelph which had been produced by a stream flowing against the front of the ice sheet.

The paper was discussed by W. M. Davis and A. P. Coleman. The former emphasized the importance of accurate phraseology in the nomenclature of glacial forms, the latter corroborated the general conclusions of Mr. Taylor in respect to the local geology.

Biserial Development in the Plates of the Arms of Crinoids: A. GRABAU, Troy, N. Y.

By means of a series of diagrams the speaker showed how the arms of crinoids begin with a uniserial set of plates, and then by the development of a series of wedge-shaped plates gradually become biserial.

The Atchison Deep Well, Kansas: E. HAWORTH, Lawrence, Kansas.

The paper was read in abstract by J. F. Kemp in the absence of the author. It described a recent deep well at Atcheson which revealed two workable coal-seams and which threw new light on the structural relation of the Coal Measures and Lower Carboniferous strata in this section.

The following papers were read by title:

Sand Crystals and their Relation to certain Concretionary Forms: ERWIN H. BARBOUR, Lincoln, Nebr.

The Broad Valleys of the Cordilleras of North America: N. S. SHALER, Cambridge, Mass.

Keewatin of Eastern Central Minnesota:

Keewenawan of Eastern Central Minnesota: C. W. HALL, Minneapolis, Minn.

Points Involved in the Silurian-Devonian Boundary Questions: H. S. Williams, New Haven, Conn.

Age of the Coals at Tipton, Blair Co., Pa.: DAVID WHITE, Washington, D. C.

Comparison between the Stratigraphy of the Black Hills and that of the Front Ranges of the Rocky Mountains: N. H. DARTON, Washington, D. C.

Tertiary History of the Black Hills: N. H. DARTON, Washington, D. C.

The Wisconsin Shore of Lake Superior: G. S. COLLIE, Beloit, Wis.

Landslides of the Echo and Vermilion Cliffs, Grand Canyon of the Colorado: RICHARD E. DODGE, New York City.

The Society then passed the customary votes of thanks to the local Fellows and with them closed a very successful meeting.

J. F. KEMP.

COLUMBIA UNIVERSITY.

ANTHROPOLOGY AT BALTIMORE.

SECTION H of the American Association for the Advancement of Science held its winter meeting at Baltimore, Maryland, on December 27th and 28th, in conjunction with the meetings of the American Society of Naturalists and Affiliated Societies.

Vice-President Butler being unavoidably absent, Professor Franz Boas was elected temporary chairman at the Thursday morning session which was called to order at 10.15 o'clock in the Historical Seminary Room at Johns Hopkins University.

The first paper read was by Dr. Thomas Wilson, on 'Anthropological Congresses at the Paris Exposition of 1900.' After a brief sketch of the history of the Congrès International d'Anthropologie et d'Archéologie Préhistorique, Dr. Wilson gave a summary of the work done at the recent sessions at Paris and described the field excursion. An account was also given of the meeting of the Congrès International des Américanistes. This Society has accepted the invitation to meet in New York city in 1902. On the motion of Dr. Wilson a committee of three was appointed to take preliminary steps for the reception of the Congress at this, its first meeting in the United States. The committee appointed consists of F. W. Putman, chairman, J. W. Powell and G. A. Dorsey.

The next paper, entitled, 'The McCormick Expedition among the Hopi,' by Dr. G. A. Dorsey, described the archeological work done along the Little Colorado River by a party from the Field Columbian Museum and by another party in the vicinity of the Hopi pueblos. The ethnological work of Mr. Voth was also described and commended. This paper will be published in SCIENCE.

Professor Franz Boas next spoke of the desirability of a catalogue of the crania now in American museums. In order that the various collections may be worked up in a uniform manner, standard skulls should be sent to each museum from which the measurements to be taken might be learned and the extent of error in observation reduced to a minimum. The Section was unanimous in its approval of Professor Boas's plan and it was voted to refer the preparation of a report upon osteological cataloguing to the Anthropometrical Committee of the Association.

Dr. Frank Russell then demonstrated a

new instrument devised for the purpose of measuring the torsion of the long bones. The features of the instrument were simplicity, ease and rapidity of manipulation and accuracy.

Dr. Walter Hough gave an ethnographic sketch of the Totonac Indians of Mexico, concerning whom but little has heretofore been known.

A second paper by Dr. G. A. Dorsey, on 'An Aboriginal Quarry in Eastern Wyoming,' closed the morning session.

Upon reassembling in the Historical Seminary Room Professor Boas withdrew from the office of chairman and Dr. Frank Russell was elected to that position.

The first paper of the afternoon was by Professor O. T. Mason, on 'Technique in Amerindian Basketry.' In the absence of the author the paper was read by Dr. Hough. All American baskets are of two types: woven or plicated and coiled. The forms of woven baskets were enumerated, with examples of each. The varieties of twined and of coiled basketry were classified and described.

Professor Boas followed with an account of his summer's work among the Kwakiutl Indians of the Northwest Coast, speaking particularly of their language. He commented upon the changes that are taking place through contact with the whites, also the change from the paternal to maternal descent in the social organization of the tribe. In the discussion which followed Dr. Fewkes pointed out the similarity between the measurements in use among the Kwakiutls and those of the Hopi, and also spoke of the customs regarding property, especially the ownership of eagles. The different clans have traditions that they came from different quarters, and the eagles' nests in those directions are not disturbed by the members of other clans.

The paper upon 'The Interpretation of Field Testimony, especially concerning Village Sites,' by Mr. W. K. Moorehead, was read by Dr. Wilson.

The Section meeting at 9 o'clock on Thursday morning in the Physical Laboratory was presided over by Professor McGee. An illustrated paper was read by Mr. Geo. G. MacCurdy, on 'Folk-Religion in Brittany.' The author described a ceremony at the church of Carnac dedicated to St. Cornély, patron of domestic animals, where live cattle are offered not only for the Saint's blessing, but also as gifts to him. At a chapel near Brussels, dedicated to St. Guidon, horses appear prominently on certain festival days. Figurines of horses and cattle used in Bohemia, Styria and Bavaria offer a striking parallelism with the Hopi figurines of domestic animals used at the winter-solstice ceremony.

Mr. Harlan I. Smith presented an illustrated paper, entitled, 'Notes upon the Archeology of the Sagwan Valley, Michigan.' These notes were selected from those taken by the author in 1890 which are now being edited for the purpose of rendering them available to the State Survey which prominent educators of Michigan are advocating. Notable among those who are endeavoring to establish an archeological survey of the State of Michigan are the University of Michigan and the Detroit Branch of the Archeological Institute of America. After discussing the paper and the desirability of extending such surveys, the Section appointed a committee consisting of Thomas Wilson, chairman, G. A. Dorsey and Frank Russell to transmit a suitable memorial to the people of Michigan expressive of its approval of the establishment of the survey.

Dr. Frank Russell exhibited a series of lantern slides made from photographs which he had taken in Arizona during the summer of 1900. This communication was avowedly presented for the purpose of eliciting information concerning the present state of our

knowledge concerning the pictographs of the southwest. In the discussion which followed Dr. Fewkes pointed out the value of these symbols to those who are studying the routes of migrations in the Southwest. He also offered interpretations of several of the characters. Dr. Hrdlička described pictographs of Northern Mexico that are suggestive of the Mayan hieroglyphs. Professor McGee reported the existence of curious pictographs which he had seen a few days before near the mouth of the Colorado River; on the top of a mesa covered with a thin layer of polished residual gravel huge figures had been traced by scraping away the gravel.

Dr. Ales Hrdlička presented the closing paper of the morning session, entitled, 'Albinos among the Hop a_d Zuñis.' A general outline of the nature of the phenomenon of albinism so far as it is known was given followed by a detailed account of the seventeen cases of albinism in the two pueblo tribes mentioned. Six of these cases are Zuñis. About two-thirds of the whole number are women. All are 'complete' albinos. Careful measurements show no inferiority in physical structure, and their slightly inferior strength is accounted for on the ground of lesser activity due to shyness. The eyes of these Indian albinos are invariably blue and not pink. No Hopi explanation of albinism was discovered. Dr. Fewkes stated that the Walpi Hopi had informed him that the people of the Middle Mesa, where the albinos are, make the 'White Paho,' prayer stick, and if a man whose wife is pregnant make such a Paho in an incorrect manner the child will be an albino. This Paho is not made at the First Mesa 'hence no albinos there.'

On Thursday afternoon Section H met with the American Folk-lore Society in the Donovan Room of McCoy Hall.

The session began with a paper by Dr. J. Walter Fewkes, entitled, 'An Interpretation of Pueblo Katcinas.' This paper embodied the results of a prolonged investigation into the character and significance of the many minor deities of the Hopi. This unique cult is regarded as a form of ancestor worship. Dr. Fewkes also exhibited a number of colored drawings that he had selected from a collection of 280 which the Hopi had made for him to illustrate the Katcinas. The value of these pictures is of course greatly enhanced by the fact that they are not only authentic, but the product of native talent.

Miss Alice C. Fletcher described 'The Lazy Man in Omaha Indian Lore.' The debate was graphically portrayed which the author once overheard in an Omaha camp, concerning the relative strenuousness of the life of the warrior of pre-Columbian days and that of the modern Indian. Their conclusion was that both must labor faithfully and continuously. From infancy the Omaha child is impressed with the direful consequences of laziness.

An interesting and valuable addition to the program was a paper upon 'The Treatment of an Ailing God,' by Dr. Washington Matthews. In the absence of the author, this paper was read by Dr. Hough.

'Hair in Folk-lore' was the subject of a paper by Mr. H. E. Warner, containing a summary of folk-sayings and tales regarding the human hair.

From the heirs of Dr. John Rae, a valuable manuscript has been received, entitled, 'Laieikawai, a Legend of the Hawaiian Islands.' This was written about thirty years ago. It was read in part by Mr. W. W. Newell. It is interesting because of the invention and dramatic power of the legend, as well as from the fact that it was written before the recent changes that tend to destroy the ancient myths.

Dr. E. W. Scripture reported that the American Philological Association and the Modern Language Association had each

appointed a committee of one to act upon a joint committee for collecting and preserving records of speech, song and similar material in various languages and dialects by means of speech-recording and transcribing apparatus. It was voted that Dr. Frank Russell be appointed to represent Section H upon this committee.

FRANK RUSSELL,
Secretary of Section H.

LELAND STANFORD JUNIOR UNIVERSITY.

WE do not think that the time has yet come when a correct opinion can be expressed in regard to the unfortunate circumstances that have recently occurred at Leland Stanford Junior University. On the one hand, 'academic freedom' is absolutely essential as a condition of higher education and research; on the other hand, academic dignity and order must be maintained. At the present time we can only publish the letters exchanged between Professor Howard and President Jordan, and the subsequent letters by Professors Hudson and Little and the reply of acting-president Branner.

On January 10, 1901, President Jordan wrote as follows:

Professor George E. Howard, Stanford University—Dear Sir: After the dismissal of Professor Ross by the authorities of this university you took occasion to make certain remarks before your class criticizing the action and the motives of the management of the university. These remarks as reported in the newspapers and credited in university circles were, in the nature of the accusations, unjust, and, in the method of their presentation, discourteous to the university management. I have waited a reasonable time in the hope that reflection would enable you to see that some explanation and apology were desirable. Failing to hear from you I now deem it my duty to request you to make satisfactory apology for this breach of courtesy and to give such assurances of your attitude toward the management of the university as will guarantee a proper harmonious relation in the future. Failing in this it is my request that you at once tender your resignation, to take effect at the end of the current year, or sooner, should your feelings in the matter prevent harmonious cooperation until that time.

Professor Howard replied on the 12th:

President David S. Jordan, Stanford University—Dear Sir: In self-defense I am forced to reply to several charges and statements contained in your letter asking my resignation. On the day following the publication of Dr. Ross' dismissal by the authorities of the university I spoke to my class in French revolution on the subject of 'Commercial absolutism and the place of the teacher in the discussion of social questions.' The address was as earnest a protest against interference with academic freedom as I was capable of making. There was absolutely no discourteous reference to the president nor to the founder, although in the discussion of the general theme there was involved a strong disapproval of their action. I do not believe that any fair-minded person who heard me will say that my remarks were discourteous in the method of presentation or unjust in their content. In the address I referred to the motives and influences which have caused the restriction of free speech in various institutions of the country. But so far as the motives and influences governing the recent action were mentioned, directly or by implication, they were those assigned in the published statement of Dr. Ross and sustained by the substance of your conversation with me on the evening of the day on which that statement appeared.

I am obliged to refer to another passage in your letter. You will scarcely fail to recall the fact that since my address before the class in French revolution you have asked me to remain in the university and repeatedly said that you did not wish me to resign. On November 20th, when our last conversation regarding the Ross incident occurred, you said positively that you should not ask my resignation unless Mrs. Stanford demanded it. How then could you have been hoping for an apology?

I have no apology to offer. My conscience is clear in this matter. What I have said I have said, as I believe, in the cause of individual justice and academic liberty. Therefore, in response to your demand, I tender you my resignation to take effect at your pleasure. An immediate answer will oblige.

On the following day President Jordan wrote:

Professor George E. Howard, Stanford University—Dear Sir: Your letter of the 12th inst., tendering your resignation as professor of history in the Leland Stanford Junior University, is duly received. I accept your resignation, to take effect at a date to be determined by you, in accordance with the concluding words of my letter of the 9th inst. These words

are: "Failing this, I request you to tender your resignation, to take effect at the end of the current year, or sooner, should your feelings in the matter prevent harmonious cooperation until that time." I shall be glad to know your further wish in the matter, and it may be communicated to Vice-President Branner, who is acting president, with full powers, in my absence.

The correspondence closed with this letter from Professor Howard, dated January 14th:

President David S. Jordan, Stanford University, Cal.—Dear Sir: Your letter accepting my resignation is received. Of course I am well aware that the rights of the large number of students now registered in my classes are involved in fixing the time of my resignation. Therefore, since I am being dismissed from a life position on the alleged ground of discourtesy to the authorities of the university, it seemed to me but fair that you should take the responsibility of saying whether I should remain to the end of the year. You decline to take that responsibility, and so leave me but one safe and dignified course.

I should have been willing to remain to the close of the year for the sake of my students, could I have felt sure that by 'harmonious cooperation' you mean a faithful and free performance of academic duty according to the spirit of the original implied contract under which I have thus far labored. I have not changed my attitude toward the university or toward my professorial duties. I am only protesting against revolutionary proceedings. The vital point of the whole present incident is a question of free speech. Therefore I am not willing to pledge myself in advance to abide by the uncertain interpretation of the ambiguous phrase 'should your feelings in the matter prevent harmonious cooperation until that time.' Hence I wish my resignation to take effect at once.

On the following day Professors W. H. Hudson and C. L. Little presented their resignations. Professor Hudson's letter reads:

President Jordan—Dear Sir: For more than a year I have for personal reasons contemplated presently severing my connection with Stanford University. Recent events now precipitate my decision to do so.

As you are well aware I was from the first in strongest opposition to the new policy of the university inaugurated in the dismissal of Dr. Ross—a policy destructive of those first principles of academic freedom upon which, as you have repeatedly said, the university was originally founded. Ever since the occurrence of that incident I have seriously doubted whether it would be possible for me, consistently with my opinions, to retain my position in this faculty. But now that in further pursuance of such policy, you have seen fit to demand the resignation of a man whom you yourself, in common with all who have known him, have long regarded as one of our ablest scholars and noblest teachers, for no other reason than that furnished by his just condemnation of the action of the university authorities—now that, in this way, you have clearly shown that it is the intention of the university to inhibit fair criticism of its methods no less than frank discussion of public affairs, no doubt is left in my mind as to my course. Whatever plans I might otherwise have made I cannot under existing circumstances continue to hold my chair. I therefore tender you my resignation, to take effect at your pleasure.

Professor Little wrote:

President Jordan—Dear Sir: Ever since the dismissal of Dr. Ross, against your protest, for expressing in the discussion of public questions opinions displeasing to Mrs. Stanford, I have considered whether I, who hold similar opinions, could be willing to remain in the faculty of Stanford University. Your recent call for the resignation of a man whose ability and independence of character I have admired for twenty years, because he uttered, in a form courteous to you and to Mrs. Stanford, condemnation of a policy destructive of the academic freedom in which you profess to believe, put an instant end to my indecision.

I hereby resign my chair as professor of mathematics in Leland Stanford Jr. University, to take effect at your convenience.

To these letters Professor J. C. Branner, acting president, replied on the same day, in identical terms, as follows:

Professor William H. Hudson, Stanford University—Dear sir: Your resignation as Professor of English literature, in the Leland Stanford Junior University, addressed to President Jordan, has been handed to me as acting president.

Waiving the question of the validity of the reasons you put forward for your action, I hereby accept your resignation, to take immediate effect.

David E. Spencer, associate professor of history, has subsequently resigned.

SCIENTIFIC BOOKS.

Text-Book of Physiology. Edited by E. A. Schäfer, LL.D., F.R.S., Professor of Physiology, University of Edinburgh. Edinburgh and London, Young J. Pentland; New York, The Macmillan Co. Vol. II.

In the preface to the first volume, issued nearly two years ago, it is stated that 'the want of a text-book in the English language to which students could turn for information beyond that contained in the ordinary manuals has long been felt by teachers of physiology (in England). 'The most extensive of the existing text-books do not aim at giving the full and precise information, nor the references to original authorities which are required by the advanced student.' The object of the work, the second and final volume of which is now before us, is to supply this want. The object is an excellent one. But when we enquire how far the editor and his able collaborators have succeeded in their laudable aim, we feel bound to answer that the execution does not in all points correspond with the design. Not that the book is devoid of good qualities. In certain respects its merits are conspicuous. No text-book of physiology in the language is more accurate. None is so extensive in its scope. Few are so scientific in treatment. But as regards its avowed purpose it labors under a serious, if not a fatal, defect. The 'advanced student' for whom it is intended scarcely exists at present. The twentieth century, which, as the newspapers have assured us, holds so many wonders in its womb, may in the fullness of time produce from the strangely miscellaneous contents of that mysterious receptacle some such miracle of precocious learning. In this year of grace 1901, he is, we fear, almost as much an abstraction as Macaulay's omniscient schoolboy. We can hardly help thinking, indeed, that whatever may have been the original plan of the book, the editor has not always been able to prevent his contributors from running away from him, or the contributors their subjects from running away with them. The consequence is that while some of the authors have evidently had in mind as their model the exhaustive 'Handbuch' of Hermann, and have treated their respective themes with a wealth of illustrative detail and a copiousness of reference which leave little to be desired for the purposes of the professional physiologist, the contributions of others are such in contents and style as a student of actual flesh and blood, who had diligently improved his time in the physiological department of a medical school of actual brick and mortar, might hope to read with intelligence and profit.

We are far from supposing that a book on the lines of the 'Handbuch,' addressed to expert physiologists, is without value. On the contrary, we believe that if Professor Schäfer and his talented coadjutors, starting with the present work as a basis, expanding what is incomplete and retrenching what is too elementary, were to develop it into a really comprehensive treatise, and do for the physiology of the beginning of the twentieth century what Hermann and his fellow-workers did for the physiology of the early eighties of the nineteenth, they would confer a greater benefit on the cultivators of the science in all lands than a dozen Richet's Dictionaries will ever do. But in order that this may be accomplished, the impossible task of crowding into 2,200 pages a far greater volume of knowledge than Hermann twenty years ago was barely able to grapple with in more than 5,000 pages, would have to be frankly given up, and the idea of combining within the same boards a book for students and a book for experts once and for all abandoned.

When all due deduction is made for the discrepancy between plan and performance, it would be unjust not to say that the work remains by far the most notable recent attempt at a systematic exposition of physiology on a large scale in any language. Upon the whole, too, it cannot be denied that the authors, while avoiding hypercriticism in handling the experimental results of others, have escaped the still more serious error of making their articles mere compilations in which all the facts that have crept into the literature are spread before the reader without indication of their relative authenticity and importance. Occasionally, however, but so rarely as to excite surprise, it would seem that the Rhadamanthus of the blue pencil must have nodded over his long task.

For instance, on p. 454 the notion that 'the close agreement between the effect upon the functional changes (in nerve) of external CO_2, and of previous nerve activity, is an indication that CO_2 is produced during the active state,' is mentioned without any warning to the innocent student that this is a mere airy speculation, such stuff, in fact, as only dreams and Croonian lectures are made of. By the way, it seems rather a pity that in a book of this size the use of such inaccurate contractions as CO_2 for carbon dioxide should have been countenanced for the sake of a petty saving of space.

On p. 499, in the account given of the changes of conductivity produced in a nerve by the passage of electrical currents it is stated that the block is established during closure at the anode and after opening at the cathode. No mention is made of the well-known experiments of Hermann and others which demonstrate that the block at the cathode during closure of a voltaic current is relatively greater than at the anode, while after opening, this relation is reversed.

On 48, the statement is made that in Stolnikow's determination of the output of the heart on the 'simplified circulation,' the output was probably maximal on account of the low resistance to the outflow. It ought not to be left to the student to supply the criticism that the heart can not have been normally fed through the coronary arteries with a pressure of only 30 or 40 mm. of mercury in the aorta, and therefore probably was not beating with normal strength. On the same page a comparison of Zuntz's results on the output in the horse, obtained by a method theoretically perfect, with those of Tigerstedt in the rabbit, obtained by a method of dubious propriety, is concluded by the remark that when the output per second is expressed as a fraction of the body-weight the results of the two observers roughly agree. The reader would inevitably draw from this passage the inference that the accuracy of Tigerstedt's numbers is supported by this agreement. The exact opposite is the case. For it is well established that the output of the heart is much greater in proportion to the body-weight in small animals than in large. If, then, Zuntz's results are right for the horse, Tigerstedt's can not be right for the rabbit.

We are glad to see that Dr. Gaskell in his article on the contraction of the cardiac muscle, written in the interesting and almost autobiographical style so characteristic of this author when he handles this theme, has at last rid himself of the picturesque hypothesis that the positive electrical variation, observed by him in the quiescent auricle of the tortoise on stimulation of the vagus, indicates 'anabolic' changes in the muscular fibers, while the negative variation seen on stimulation of the augmentor nerves of the quiescent ventricle of the frog or toad indicates 'katabolic' changes, and has adopted the more prosaic view of other writers, that the electrical changes are simply associated with alterations in the tone of the heart muscle too small to be easily seen.

The contributors to this and the previous volume include most of the prominent workers in English physiology; and nearly all write upon subjects the knowledge of which they have advanced by their own labors. Thus, Dr. Leonard Hill, in one of the best articles in the book, treats of the circulation; Sir J. Burdon Sanderson, of striped muscle, including the electrical phenomena of this tissue, in the investigation of which he stands facile princeps in the English-speaking world; Professor Gotch, of nerve and electrical organ; Professors Schäfer and Sherrington, of the central nervous system; Dr. Langley, of the sympathetic and allied systems; Professor Haycraft, of animal mechanics, taste and smell; Professor McKendrick and Dr. Gray, of the ear and voice; Professor Starling, of the muscular and nervous mechanisms of the digestive tract, etc.; and Dr. Rivers, of vision.

G. N. I. S.

Die Lehre vom Skelet des Menschen, unter besonderer Berüchsichtigung entwickelungsgeschichtlicher und vergleichend-anatomischer Gesichtspunkte und der Erfordernisse des Anthropologischen Unterichtes an höheren Lehranstalten, bearbeitet. Von DR. F. FRENKEL, Professor am Königl. Gymnasium zu Göttingen. Mit 81 Textfiguren. Jena, Gustav Fischer. 1900.

We have given the title at length, cumbersome as it is, because it expresses the nature of the work, and because this book has the merit of being what it pretends to be. More than that, it is the successful working out of a well-considered and philosophical plan. The purpose, in short, is to offer to students a guide to the general principles governing the morphology of the human skeleton, considered according to development and comparative anatomy. The great beauty of the book is the subordination of details to principles. It does not teach the bones as they must be taught to a student of medicine, but we wish that all medical students could have been put through this book before the beginning of their medical studies.

With the bones are very properly considered both cartilages and ligaments. It is not the disjointed skeleton that is before us, but the real framework of the body. There is first a short chapter on the histology of bone and the other connective tissues involved, and then we begin the development of the skeleton from the *chorda dorsalis*. Then we have the shapes of bones, their connections, the development of joints and the various kinds. Then we come to the description of the particular parts of the skeleton with the scientific significance dwelt upon and the details suppressed. What a relief from the compendium of anatomy which thinks well of itself because it gives the several surfaces of the orbital process of the palate bone! On the other hand, to take one example of many, how interesting to have the comparative anatomy of the malar bone!

It is not necessary to discuss the book in further detail. There are many morphological questions concerning which different opinions may be held, and an author is not necessarily wrong even if the reviewer should not agree with him on all points. That the plan of the book is good and that the aim of the author has been true is praise enough. We will add, that we wish someone would 'do it into English.'

THOMAS DWIGHT.

HARVARD MEDICAL SCHOOL.

Evolution of the Thermometer, 1592–1743. By HENRY CARRINGTON BOLTON. Easton, Pa., The Chemical Publishing Co. 1900. 98 pp.

This neatly printed and tastefully bound little monograph will be of interest to all physicists and chemists, and to the general public as well, for it deals with one of the most indispensable instruments in every laboratory, and one which, almost alone of those used by scientific men, has become an instrument of interest and use in every household.

In dispelling the fallacies and clearing away the obscurities which have enveloped the evolution of the thermometer, Dr. Bolton has again placed scientific men under an obligation, while at the same time he has afforded them an hour's entertaining reading.

The book opens by disposing of the oft-repeated claims that the inventor of the thermometer was Drebbel. The first use of the name, thermometer, and the first accurate description, comes from Leurechon in 1624, but the real inventor of the instrument was Galileo, and the date between 1592 and 1597. This is proved, not from any statements of the inventor, but from letters written to him, and the proof is complete. This first thermometer consisted of a bulbed tube, inverted in colored water, in which the liquid rose and fell with the temperature of the bulb. With such an instrument Sanctorius discovered that there was a normal body temperature. In 1632 Jean Rey made a water thermometer, in which the expansion of a fluid replaced that of air, and not long after this Ferdinand II. of Tuscany, by sealing the top of the tube, gave approximately the modern form to the instrument. Mercury had been previously used to show expansion by heat, but in 1714 Fahrenheit constructed the first mercury thermometer with a reliable scale.

Many different scales have at various times been applied to the thermometer, and in most of them the graduation has been almost purely arbitrary. The origin of the Fahrenheit scale is involved in much obscurity. Réaumur was the first to use the melting point of ice for zero, while his boiling point of water, 80°, was obtained by the expansion of one thousand parts of 80 per cent. alcohol between the freezing and boiling points of water. As this was eighty parts, he used this number for his higher fixed temperature. The first to adopt 0° and

100° for the two points was Celsius, but in his instrument 0° represented the boiling point of water. Finally the change to the modern centigrade scale was made independently by Christin of Lyons and Strömer of Upsala, in 1743. With this date, Dr. Bolton's story of the evolution of the thermometer ends.

At the close of the book is given a table of the relative values of thirty-five different scales which have been used at various times; a chronological epitome; a list of authorities, and an index to the book.

BOOKS RECEIVED.

A Treatise on Elementary Dynamics. H. A. ROBERTS. New York and London, The Macmillan Company. 1900. Pp. xi + 258. $1.10.

An Introduction to Modern Scientific Chemistry. LASSAR-COHN. Translated by M. M. PATTISON MUIR. New York, D. Van Nostrand Company. 1901. Pp. viii + 348. $2.00.

The Foundations of Botany. JOSEPH Y. BERGEN. Boston, Ginn & Company. 1901. Pp. x + 412; v + 257.

SCIENTIFIC JOURNALS AND ARTICLES.

IN the November–December number of the *Journal of Geology* James Perrin Smith discusses the 'Principles of Paleontologic Correlation.' He lays great stress on interregional zones and concludes that correlations upon homotaxis and synchronism should not be very different. Under 'Contributions from Walker Museum' E. C. Case describes 'The Vertebrates from the Permian Bone Bed of Vermillion County, Illinois.' A forty-page article by C. R. Van Hise on 'Some Principles controlling the Deposition of Ores' discusses the concentration of ores by underground water. He urges a new and natural classification of these ore deposits based upon their genesis, believing that such a division would also be of the greatest importance in the practical problems of engineers.

THE contents of the *Journal of the Boston Society of the Medical Sciences* for December 4, 1900, are as follows: 'Demonstration of a Photomicrograph of the Bacillus of Soft Chancre,' by F. B. Mallory; 'The Etiology of the Chancroid,' by Abner Post; 'A Simple Method of cultivating Anaërobic Bacteria,' by James H. Wright; 'Occurrence of the Typhoid Bacillus in Suppurative Processes and in the Fœtus,' by Oscar Richardson, being the annotated record of a number of cases, and 'Observations on Milk Coagulation and Digestion,' by Franklin W. White.

The Plant World for December, 1900, opens with a popular article on 'Irises,' by F. H. Knowlton, in which he notes that there are about 160 species, and W. J. Beal presents, with illustrations, 'A Few Observations on Root Hairs'; Arthur Hollick gives 'An Example of Deductive Reasoning,' this being that the bottom deposits in a small swamp on Staten Island should represent the Quaternary age, a deduction that was verified by the excavation of the swamp. Edward Hale Brush gives some notes on 'Horticulture and Landscape Gardening at the [coming] Pan-American Exposition.'

The Auk for January contains two biographical sketches, 'In Memoriam: Elliott Coues,' by D. G. Eliot, and 'In Memoriam: George Burritt Sennett,' by J. A. Allen, both accompanied by portraits. Outram Bangs gives some observations on 'Birds of San Miguel Island, Panama,' incidentally describing four new species. James H. Fleming presents 'A List of the Birds of the Districts of Parry Sound and Muskoka, Ontario,' comprising 196 species, and E. W. Nelson gives 'Descriptions of Five New Birds from Mexico.' 'The Sequence of Moults and Plumages of the Laridæ' (Gulls and Terns) is discussed by Jonathan Dwight, Jr., a subject that has received little attention, save at the hands of Brehm, in 1854. John H. Sage, the secretary, has an abstract of the 'Eighteenth Congress of the American Ornithologists' Union.' The 'Report of the Committee on the Protection of North American Birds for the Year 1900,' by Witmer Stone, shows that while much has been accomplished, a great deal remains to be done, and that decided help may be hoped for from the recent 'Lacey Bill.' William Dutcher gives the 'Results of Special Protection to Gulls and Terns obtained Through the Thayer Fund,' the expenditure of $1,400 having resulted in the preservation of many birds.

Terrestrial Magnetism for September, which has just appeared, contains a portrait and biographical sketch of Professor Arthur Schuster. Among other articles in the number are 'The Present Status of our Knowledge of the Earth's Magnetism,' by A. Nippoldt; and 'Note sur une cause d'erreur dans la détermination de la déclinaison magnétique,' by H. Morize.

THE first number of the *Journal of Hygiene*, published by the Cambridge University Press and edited by George H. F. Nuttall, lecturer in bacteriology and preventive medicine in the University of Cambridge, late associate in hygiene in the Johns Hopkins University, Baltimore, is announced for immediate issue. The provisional table of contents is as follows:

'Introductory' by Sir John Simon, Professor William Osler and the Editor.

'Studies in Relation to Malaria.'

I. 'The Geographical Distribution of Anopheles in Relation to the Former Distribution of Ague in England,' by G. H. F. Nuttall, Louis Corbett and T. S. Pigg.

II. 'The Structure and Biology of Anopheles,' by G. H. F. Nuttall and Arthur E. Shipley.

'Pathogenic Microbes in Milk,' by E. Klein.

'Industrial Lead Poisoning,' by T. M. Legge.

'A Rapid Method of determining Carbonic Acid in Air,' by John Haldane.

'The Cause of the Red Color in Salted Meat,' by John Haldane.

'Artificial Modifications of Toxines, with Special Reference to Immunity,' by James Ritchie.

La euille des jeunes naturalistes, edited by Mr. Adrien Dollfus, 35 Rue Pierre-Charron, Paris, having existed thirty years, has taken the opportunity of improving its appearance and intends to concentrate its efforts mainly on the natural history of western and central Europe with the adjacent regions around the Mediterranean. The library at the disposal of subscribers to *La Feuille* now contains about 42,000 memoirs and 300 scientific journals. The November, December and January numbers, which are those that have as yet appeared of this new series, amply fulfill the promise made. The most notable article is 'Revision des espèces de Tritons du genre *Euproctus* Gené, suivi d'un aperçu des Urodèles de la région paléarctique du sud-ouest,' by Dr. W. Wottersdorff.

SOCIETIES AND ACADEMIES.

NEW YORK ACADEMY OF SCIENCES.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY.

A REGULAR meeting of the Section was held at 12 West 31st St., New York, on the evening of January 7, 1901. Professor Harold Jacoby, of Columbia University, gave an account of a 'New Telescope for Photographing the Pole of the Heavens.' He announced that this plan of photographing the close polar stars had made material progress. A special instrument has been constructed and mounted at the Observatory at Helsingfors, Finland. Photographs of the actual instrument in position for use were exhibited. It is planned to make photographs with this instrument in which the close polar stars will trace out 'trails' on the plate corresponding to their diurnal motion. The effects of refraction, etc., having been eliminated by computation, it is possible to obtain from such photographs the exact position of the celestial pole among the stars and on the date of observation. The intercomparison of results taken on dates six months apart should furnish a new determination of the constant of aberration, and photographs taken annually throughout a series of years should determine the constant of nutation and ultimately perhaps even that of precession.

The actual observing with the instrument will commence in the spring, as soon as the Helsingfors astronomers have finished with the observations of Eros now in progress, and the plates will be sent to Columbia University, New York, for measurements and reductions. An outline of the method to be used, together with a preliminary trial of the same, has already been published by Professor Jacoby, under the title 'Photographic Researches near the Pole of the Heavens,' *Bulletin of the Imperial Academy of Sciences of St. Petersburg*, 5th Series, Vol. 9, p. 41, June, 1898.

Mr. George B. Pegram, of Columbia University, read a paper on the 'Reflection of Light from White Surfaces.' This was an experimental study of some white surfaces with regard to the relation between the intensity of the reflected ray and the angles of incidence

and reflection. It was carried out by means of a special photometer, allowing the use of any desired angles of incidence and of reflection. Among the surfaces tested were plaster of Paris, several kinds of unglazed paper, compressed powders of several kinds, powders not compressed, but gently smoothed with a metal plate, and finally a surface made by allowing fine plaster dust to settle from suspension in the air on a suitable plate. These surfaces in the order named, showed decreasing polarization of the reflected light, and less approach to specular reflection. The fine dust surface showed no polarization, and almost no tendency to regular reflection. The results with this surface, as shown by sets of curves, follow pretty closely the old Lambert's, or cosine, law,

$$\text{Intensity} = A \cos i \cos r.$$

with some departure when both angles were very large. With all the other surfaces the departure was very great for angles greater than 70°. Contrary to the results of Mr. Wright (*Phil. Mag.*, Feb., 1900), these experiments were quite in accord with the demand of theory that the intensity of the reflected ray should be expressed as a symmetric function of the angles of incidence and reflection.

WILLIAM S. DAY,
Secretary.

CHEMICAL SOCIETY OF WASHINGTON.

THE regular meeting was held on December 13, 1900. The first paper was read by Dr. Bigelow and was entitled, 'The Composition of the Ash of Meat Extracts,' by W. D. Bigelow and E. McK. Chace. The relation between solids and ash and between the several ash constituents were discussed in analyses of about 40 commercial meat extracts and of juices prepared from fresh beef.

The second paper, read by Dr. Cameron, was entitled, 'Formation of Sodium Carbonate or Black Alkali by Plants,' by F. K. Cameron. The view popularly held, to which Hilgard, Goss and others have called attention, is found to be correct. It seems probable that the phenomenon is very widespread, but does not assume practical importance, except under special conditions in the arid regions. A discussion of the rôle of mineral nutrients in soil solutions accompanied the consideration of the data experimentally determined.

The last paper, read by Dr. Cameron, was entitled, 'Resistance by certain Plants to Black Alkali,' by F. K. Cameron. It has been found that a few plant specimens exist which can grow in soils containing much sodium carbonate. Three such plants were examined. It was found that these plants had an organic acid or acids formed on their surface, sufficiently strong to decompose alkaline carbonates. It is believed that this acid, or acids, aid in lowering the concentration of the alkaline carbonates in the soil immediately about the plants, and thus protect the root crowns from the caustic action of the black alkali.

WILLIAM H. KRUG,
Secretary.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 527th meeting was held January 5th, the new President, Mr. Walcott, Director of the Geological Survey, in the chair. The evening was devoted to geodetic papers.

Mr. Eimbeck presented informally the question of an apparent error arising in transit observations from the fact that at a locality where there is local attraction of the plumb line the geodetic meridian and the astronomical meridian differ sometimes as much as 30″.

The first regular paper was read by Mr. Isaac Winston on 'The Thirteenth General Conference of the International Geodetic Association,' held at Paris last fall, at which 17 countries were represented, and to which he was a delegate. The principal papers presented there dealt with recent work at gravity stations, the question of variation of latitude, the proposed revision of older triangulations in France and Peru, the nickel-steel alloy with small coefficient of expansion, and the recent and prospective measurements of terrestrial arcs. [This paper is printed above.]

Mr. Schott followed with an interesting historical account of such measurements, pointing out that the Clarke spheroid agreed better than Bessel's with the American observations. Mr. Hayford described more fully the simple new nadir-zenith apparatus of Cornu, to which ref-

erence had been made, the purpose of which is to determine the zenith distance of stars culminating very near the zenith.

The second regular paper was by Mr. Hayford on 'The New Precise Leveling Instrument' of the Coast and Geodetic Survey, with exhibition of it. The instrument is very low and stable, the new iron nickel alloy is used, the level tube is sunk well into the telescope tube, the parts are not reversible as formerly, and an auxiliary telescope with mirror is provided for the left eye to read the ends of the bubble. Field experience shows that both rapidity and accuracy of working have been much increased by the use of the new instrument. [The full description will be published elsewhere.]

Charles K. Wead,
Secretary.

DISCUSSION AND CORRESPONDENCE.

WHOSE FAULT AT THE U. S. NAVAL OBSERVATORY.

To the Editor of Science: It is natural and very proper that the Superintendent of the Naval Observatory should defend his institution, even vigorously, against charges, where he conceives there is ground for believing there has been lack of fair play. The delicate task imposed upon the Board of Visitors should evidently have been sufficient motive for safeguarding their report against the suspicion of unfairness, if any has been shown, by first giving full credit to the existing organization in preparation for their suggestions looking to an improvement. Otherwise, the entire affair will degenerate into a dispute, and that is the most hopeless basis upon which to approach Congress for remedial legislation.

Your editorial in Science of January 4, 1901, on the 'Naval Observatory Report' does not seem to be free from the objection that it charges against the administration of the Observatory certain results which do not in reality belong there. You blame it for the removal of the Magnetic Observatory to its present site, and for the imperfections of the instrumental apparatus acquired during the past thirty years. It is very easy to misplace responsibility, but in a discussion of this kind it ought not to be done; and the fact is admitted that in such matters of administration the executive acts upon the advice of his subordinates. Now, certainly, there could not be two more conspicuous examples chosen to show that, where the astronomers have had their own way, the blame is being shifted to the chief. For it is well known that the magnetic observatory was moved by the counsel of the Astronomical Director, in cooperation with that of a prominent visiting English astronomer, and against the arguments of the professor in charge of the magnetic work, and all others in Washington interested in magnetic observations. The action of neighboring trolleys and dynamos was pointed out, but the wish to possess the equipment overruled the interests of science. The fact that the work of the magnetic observatory has not been otherwise efficient is partly due to the appointment of untrained officers of the Navy to conduct the operations, and this is of course a matter of administration. In the planning of new instruments the astronomers have for a long while had their head, and if they chose to experiment in novel constructions and to entrust the building of the instruments to American firms, they ought at least to relieve the administration, which simply expressed their decisions, of the blame for an unsatisfactory outcome of that kind.

This brings up the problem of administration. There are two types of organization, the first, where there is a strong head and a corps of subordinates who are his assistants, and over whom his decisions are final, of which the observatories at Cordoba and Harvard College are examples; then there are staffs formed of practically independent professors whose real bond of union is cooperation, of which the Naval Observatory is an example; other observatories have a mixed system in operation. The first type is calculated to put out a large mass of routine work, and to do immense pieces of observation and reduction along well-understood simple lines; the second type is suited for scientific researches into unexplored territory, where the initiative and the successful progress depends entirely upon the personality of the astronomer. No chief by executive order can aid his research, and the heads of institutions are always only too glad to support the work of men

who show real capacity, and the persistency required to bring things to a conclusion. This type of organization is the one in keeping with the highest requirements of modern science, where a work is allotted by choice or natural selection to a man, and he is given the opportunity to develop it. If in such a body of men cooperating for a common good, there should enter jealousy, dissension and rivalry, the end will be defeated, but by no fault of the system. The astronomers of the United States should consider seriously whether it is wise to debase an organization which gives the utmost possible freedom to the individual astronomer, and supplant it with a scheme where authority at the top limits the scope of operations to the will of one man.

The executive in the large Government surveys is so far burdened down with administrative duties, finances, correspondence, mediation between Congress and the public, that it is quite impracticable for him to devote energy to the advanced problems of the day. A scientist can take up these duties only by abandoning his researches, and it is little more than a dream to suppose that one can carry both along together. The proper attitude is that of cooperation between the administrator and the astronomer engaged in practical research, and I am quite persuaded that the officers of the Navy, in the Bureau and at the Observatory, have been quite as faithful to their duties as the astronomers to their tasks. Lack of cooperation, from whatever cause it may arise, is not to be remedied by legislation; this may destroy the free chance to cooperate by introducing subordination, but it would be a step backward, and it should be taken only when a body of American astronomers can not be selected, who are willing to make the most of their splendid opportunities. Furthermore, the attachment of the Observatory to the Navy Department has been the source of its prosperity, in that it has thus secured liberal and generous congressional action through half a century. Now Congress has not yet felt that its duty lies in establishing and supporting an astronomical observatory for research only, no matter how valuable this might be to the world at large. Its theory is that a practical *quid pro quo* must be given for the people's money. The fact that the Navy needs a Nautical Almanac and a time service, and that these are practical utilities has been the ground for the annual appropriations. There is no other Department of the Government better fitted to press such claims upon Congress than the Navy, and to abandon this utilitarian ground would be to diminish the financial resources of the institution. As matters now stand there is no prospect of being able to persuade Congress to support such a research observatory; under the circumstances the nearest we can come to it is the free cooperation of the astronomers in the Naval Observatory. If these 'lay down' behind their commissions, or if their 'human nature' is too much for their good sense and the progress of science, there is no question where the responsibility should be placed. If it be true that the past generation at the Observatory, consisting of able, honorable men, failed to accomplish all they expected to do, may we not hope that the spirit of mutual cooperation between the executive and scientific staff, and the professors one with another, may still be the true remedy, rather than an angry discussion or any type of restrictive legislation which could be devised?

FRANK H. BIGELOW.

WASHINGTON, D. C., January, 10, 1901.

POTASSIUM NITRATE IN WYOMING.

LAST fall Mr. Victor Milward, of Dayton, Wyoming, sent me a small package of mineral which he wished tested for nitrates. The sample was a dark brown color, pulverent and contained a large amount of sand. Upon testing the substance I recognized that it was a nitrate and, in looking for the base, potassium was found in unusual quantities. Mr. McClelland an instructor in this department made a preliminary analysis and found that the sample contained upwards of fifty per cent. of potassium nitrate, and that it was nearly pure. Sodium was not detected. Mr. Milward was informed of his discovery and encouraged in making further investigations, and also asked to furnish some data as to his discovery and its extent. Later a number of samples of dark colored sandstone were received, that had been taken from

various depths and also a specimen from the surface of the prospect. The samples did not contain any of the salt except the one taken from the very surface. On this the nitrate was a coating about a quarter of an inch in thickness, and, as the previous sample sent, was approximately pure potassium nitrate. So far, the salt found is in very limited quantities and there are no explanations to offer for its existence or accumulation. It is evident that it has been brought in and deposited upon the sandstone but the source has not been detected. Owing to the winter months being close at hand when the discovery was made, it was not possible to carry on any extended examination. Potassium nitrate has been found in very minute quantities in the Leucite hills by Cross; this, however, is the most important discovery ever made in the State, and may result in the location of nitrate deposits of commercial importance.

CURRENT NOTES ON PHYSIOGRAPHY.

SOUTHERN WISCONSIN.

'THE Geography of the Region about Devil's Lake and the Dalles of the Wisconsin' by R. D. Salisbury and W. W. Atwood (*Wis. Geol. and Nat. Hist. Survey*, Bull. v, Educational series, 1, Madison, 1900), is a significant publication if for no other reason than that it is concerned with geographical features and that it is a State publication 'primarily designed for use in the schools.' State surveys have been very slow in coming to recognize their responsibility in this direction; and we are glad to see Wisconsin now following Missouri, New Jersey and Maryland. The region described includes a typical resurrected mountain, Baraboo ridge, of Huronian quartzite, adjoined by a plain of erosion, too smooth over much of its extent to be called a peneplain, formed by the removal of paleozoic strata which once buried the ridge, and which still remain in isolated castle-like hills here and there over the plain, and more continuously in hilly uplands farther southwest. The Dalles of the Wisconsin river are cut in the plain where the river has been displaced by glacial action from its former course. The 150 pages of the report are illustrated by 38 plates and 47 figures, and closed with a good index.

THE ISLANDS OF SOUTHERN CALIFORNIA.

'A TOPOGRAPHIC Study of the Islands of Southern California,' by W. S. Tangier Smith (Bull. Dept. Geol., Univ. Cala., ii, 1900, 179–230) presents additional details concerning the features of this interesting group. The author points out that on a single shore line a wave-cut terrace of much strength may be developed where the coast has a moderate resistance and gentle slope, while hardly any shore marking is made where the coast is more resistant and of steeper slope. On San Clemente the rocks are relatively resistant and the general slope of the island is moderate; here wave-cut terraces at various levels have been remarkably developed and wonderfully preserved.

The occurrence of such terraces suggests some observations regarding the origin of those plains of erosion which now stand somewhat above sea level and are moderately dissected by streams, as in the Piedmont district of eastern Virginia and in the peninsula of Brittany. On both these plains the broad uplands are sheeted over with heavy soils of local weathering; the valleys that dissect the uplands are narrow and steep-sided. If the plains were of subaërial origin the abundant soils would be an appropriate feature; if the plains were the result of marine abrasion, the soils must have been developed by weathering on the wave-cut rock floor in the same period of time as that required for the erosion of the narrow valleys. The terraces of San Clemente may perhaps afford means of comparing the rate of soil production and valley erosion, and thus of giving further evidence regarding the origin of the districts in question.

DEECKE'S ITALIEN.

A WORK on the general geography of a country should not be criticised too closely with regard to its physiographic chapters, for there are many other lines toward which the chief interest of the author may have been drawn more strongly. It is nevertheless instructive to examine the method of treating land forms

that is found acceptable in an important volume of a new series of geographical handbooks. Deecke's work on Italy * treats in its first chapter the limits and area of the country ; in the second, the surrounding seas ; in the third, the history of exploration ; relief in the fourth, geological structure in the fifth, and climate and hydrography in the sixth and seventh. Then after 250 pages devoted to population, history, products and commerce, government and religion, the remaining 125 are given to the description of provinces ('Chorography'). In comment on this order, it may be said that it is not satisfactory from a physiographic standpoint to give a leading place to relief and a following place to geological structure; in such an order, relief must be treated empirically and to that extent imperfectly. Under hydrography many interesting details are given concerning certain rivers which have changed their courses in historical time—the Adige, the lower Po, and the Chiana between Tiber and Arno—but the development of rivers is hardly considered. The provincial descriptions include much material of value, yet they omit many facts that would shed useful light on local topography. Taken all together, the book is certainly good, but it does not contribute much to the development of the new scheme of geographical treatment that it is to be hoped may characterize similar works in the new century.

NORWAY.

A HANDSOME volume entitled 'Norway, official publication for the Paris exhibition, 1900' (Kristiana, 1900, 626 + xxxiv p., many plates, figures and maps) contains valuable chapters on topography, by Hansen; geology, by Reusch; and climate, by Steen, occupying 50 pages ; the rest of the volume being given to history, social conditions, commerce, etc. Hansen gives a just emphasis to normal and glacial erosion in his account of surface features. The highland is described as an immense mountain plateau, whose 'even summits clearly indicate that it was originally a plain of denudation that has afterwards been forced up into an arch.' The summits that tower above it, being of harder rocks, may be supposed to have withstood the destructive forces which leveled the remainder. 'Actual connected mountain chains rising above lowlands at both sides do not exist.' Canyon like valleys, cut in the uplifted highland, were modified by strong glacial erosion, producing fiords. The mountains that rise above the highland frequently have sharp alpine forms with corries (botner) which are described as having been developed in névé fields above level of the glacial sheet. The glaciated area exposes bare rock over so much of its surface as stands above the old shore line that marks post-glacial submergence ; but below this line there are abundant sands and clays, affording arable land. The population is largely found below this level.

The relation of Norway to Sweden is interestingly presented. Although the two countries border each other along a boundary line that measures a thousand miles in length, by far the greatest part of this line lies on the uninhabited mountainous highland. The two countries are therefore separated rather than joined. Only three railroads and about a dozen highways cross the boundary. In 1898, only five per cent. of Norway's goods-exchange crossed the land frontier by railway and only one third of one per cent. by other means, while ninety-five per cent. went by sea.

WM. DAVIS.

* 'Bibliothek der Länderkunde' herausgegeben von Dr. A. Kirchoff und Dr. R. Fitzner. Berlin, Schall. 'Italien' von Professor Dr. W. Deecke, 1898.

UNITED STATES BOARD ON GEOGRAPHIC NAMES.

THIS Board, to which is referred questions of disputed geographic nomenclature arising in the Executive Departments of the Government, held its monthly meeting January 9th. Philippine Island names were considered at some length. The Coast and Geodetic Survey is about to issue an atlas of the Philippine Islands. This atlas will contain about thirty maps made by Jesuit missionaries in the islands. It is preceded by an introduction, which, among other things, has three lists, comprising in all about 6,000 geographic names. These names are now in the final proof stage. The list was prepared and the proof corrected by Rev. Father Algue, S.J., of Manila, but who has been

spending the winter in Washington. The Coast and Geodetic Survey asked the Board to adopt this list of names. The United States Hydrographic Office had previously submitted a manuscript list of about 4,000 coastwise names which list had been compiled in that office and asked for its adoption by the Board. To that request the Board had responded by recommending that it be submitted to Father Algue for comment, correction and criticism. This list with Father Algue's criticisms, together with the Coast and Geodetic Survey list was presented and discussed and, as the outcome, both lists were referred to the Hydrographic Office for comparison with a view to discovering cases of discrepancy.

The Board proceeded with its usual routine cases, deciding 21 of them. Most of these are minor features in different parts of the country, and thus of only local interest. For example, whether it is Bobs or Bobbs, Douglas or Douglass, Mullin or Mullen, Reem or Reams, etc. Such cases are for the most part easily disposed of by getting, by correspondence, local information.

Two or three cases were of wider interest. For a county in Idaho the Board adopts the form Nez Perce (not Nez Perces) conformably to the uniform practise in that county and in Idaho. For a river in southwestern Iowa the form Nishnabotna was adopted in place of several other forms which have been more or less used. For three glaciers in Glacier Bay, Alaska, were adopted the names Carroll (not Woods), Grand Pacific (not Johns Hopkins), and Rendu (not Charpentier). All these names, including the rejected forms, are still in use, but there has been confusion in their application. The Board follows the original usage as printed on Coast and Geodetic Survey map No. 3,095 (edition of July, 1899).

Finally, one more case in Alaska may be mentioned. The easternmost point of Kadiak is supposed to be the one seen by Bering in 1741 and by him called St. Hermogenes; on some charts written Hermogenes. Cook in 1778 called it Greville. Some of the Russian charts call it Yelovoi (spruce) and others Tolstoi (broad). Its supposed native name is Chiniak, which on one chart has appeared as Tuniak. The present local usage is reported to be Chiniak and this was adopted by the Board.

SCIENTIFIC NOTES AND NEWS.

The Geological Society of London has made the following awards for 1900: Wollaston medal, Dr. C. Barrois, Secretary of the International Geological Congress. Wollaston fund, Dr. A. W. Rowe, for papers on zonal geology and paleontology of the chalk of England; Bigsby medal, G. W. Lamplugh, of the British Geological Survey. Murchison medal to A. J. Jukes-Browne, of the same. Murchison fund, to T. S. Hall, of Melbourne, for work on the Tertiary Geology of Victoria. Lyell medal to Dr. R. H. Traquair, pal-ichthyologist of Edinburgh. Lyell fund to be divided between Dr. J. W. Evans, for work on Indian geology, and A. McHenry, of the Geological Survey of Ireland.

William H. Crocker, of San Francisco, has offered to defray the expenses of a solar eclipse expedition to be sent by the University of California from the Lick observatory to Sumatra to observe the total eclipse of the sun on May 17th. An astronomer and assistants will sail from San Francisco on February 19th to be absent until July. They will establish an observatory camp somewhere within twenty miles of Padang, on the west coast of Sumatra.

At the recent International Congress of Hygiene and Demography a committee was appointed on the hygiene of streets, of which Dr. R. Hering of New York is the American member.

Among the honors conferred by Queen Victoria for the New Year are the K.C.B. on Sir William Turner, professor of anatomy in the University of Edinburgh, and baronetcies on Dr. William Church, president of the Royal College of Physicians, and Dr. Thomas Barlow, a London physician.

Professor E. von Drygalski, of the University of Berlin, has been elected an honorary corresponding member of the Royal Geographical Society of London.

The Spencer Lens Company, Buffalo, N. Y., of which Dr. Roswell Park is president, announces that it has placed its scientific

department in charge of Dr. Hermann Kellner, who has been associated with Professor Abbe in the optical works of Carl Zeiss at Jena. Mr. Carl F. Dieckmann, who has also been employed at the Zeiss optical works, has been engaged as superintendent.

DR. BUSHROD W. JAMES, of Philadelphia, has been elected president of the Pennsylvania Fish Protective Association.

MR. G. T. HASTINGS, who was last year assistant in botany in Cornell University, is this year teacher of science in the English Institute, Santiago, Chili. Mr. Hastings's engagement is for five years, and during that time he expects to make a thorough study of the flora of the region.

DR. VICTOR C. VAUGHAN, professor of hygiene in the University of Michigan, has been appointed to a third term as member of the Michigan State Board of Health.

PROFESSOR E. F. BUCHNER, of the department of psychology of New York University, has been elected an honorary member of the new French Société Libre pour l'Étude Psychologique de l'Enfant, of which Professor F. Buisson, of the Sorbonne, is president.

THE Science Club of Northwestern University held its last meeting on the evening of January 11th. The Club was addressed by Professor A. V. E. Young on 'A Century of Discovery among the Elements.'

PROFESSOR WILLIAM HALLOCK, of Columbia University, gave on January 22d the second address before the Washington Academy of Sciences on the 'Progress and Tendency of Science during the Nineteenth Century,' his subject being physics.

DR. DAVID T. DAY, of the United States Geological Survey, is giving a series of Columbia University lectures at the American Museum of Natural History on Saturday evenings, as follows: January 5th, 'The Mining Outlook of the Opening Century'; January 12th, 'The World's Mineral Wealth as shown at the Paris Exposition'; January 19th, 'The Petroleum Industry of the United States'; January 26th, 'The Mineral Resources of Cuba, Porto Rico, Hawaii and the Philippines.'

THE Friday evening meetings of the Royal Institution of Great Britain opened on January 18, 1901, when Professor Dewar was expected to give a lecture on 'Gases at the Beginning and End of the Century.'

DR. HARTINGTON, who has been relieved from the position of head of the medical department of the University of West Virginia by the Board of Regents, has brought suit to recover $25,000 from the president of the University.

THE death is announced of M. Charles Hermite, the eminent French mathematician, at the age of seventy-eight years.

THE death is also announced at the age of seventy-five years of Dr. Potain, professor of medicine at various institutions in Paris since 1876, member of the Academy of Medicine since 1882, and of the Academy of Sciences since 1894.

THE position of hydrographic draughtsman in the U. S. Coast and Geodetic Survey, at a salary of $600 per annum, will be filled by Civil Service examination on February 5th and 6th.

WE are requested to state that a young Russian gentleman, now living at St. Petersburg, who has done excellent work in physics and bacteriology, desires to find a position in the United States in the field of physiology or the applications of physics. Those interested in this matter will do well to correspond directly with His Excellency, Dr. H. Wild, 56 Englisch Viertel-Str., Zurich, Switzerland, or with Professor Cleveland Abbe, Washington, D. C.

THE Carmichael prize of the Royal College of Surgeons in Ireland, which is of the value of £120, has been awarded to Mr. H. Nelson Hardy, F.R.C.S.Ed. for an essay dealing with the state of medicine, surgery and pharmacy in the United Kingdom.

THE Astley Cooper triennial prize of £300 will be awarded by Guy's Hospital, London, for an essay on 'The Pathology of Carcinoma and the Distribution and Frequency of the Secondary Deposits corresponding to the Various Primary Growths.' The essays should be sent to Guy's Hospital on or before January 1, 1904.

THE New York Zoological Society has presented the American Museum of Natural History with the following specimens: A young

moose (*Alces americanus*), an equine deer (*Cervus equinus*), an orang utang (*Simia satyrus*), a loris (*Nycticebus tardigradus*), an ocelot (*Felis pardalis*), three bay lynxes (*Lynx ruffus*), a jaguarondi (*Felis jaguarondi*), two black leopards (*Felis pardus*), a raccoon (*Procyon lotor*).

At the 526th meeting of the Philosophical Society of Washington, held December 22, 1900, in the assembly room of the Cosmos Club, the following officers were elected for the calendar year 1901: *President*, C. D. Walcott, Geological Survey; *Vice-Presidents*, R. Rathbun, Smithsonian Institution; J. H. Gore, Columbian University; C. Adler, Smithsonian Institution; E. D. Preston, Coast Survey; *Treasurer*, B. R. Green, Library of Congress; *Secretaries*, J. F. Hayford, Coast Survey; C. K. Wead, Patent Office; *General Committee*, W. A. DeCaindry, War Department; G. W. Littlehales, Hydrographic Office; H. M. Paul, Navy Department; F. W. True, National Museum; I. Winston, Coast Survey; J. E. Watkins, National Museum; J. G. Hagen, Georgetown Observatory; C. F. Marvin, Weather Bureau; L. A. Bauer, Coast Survey.

At the annual meeting of the Anthropological Society of Washington, on January 8th, the following officers were elected: *President*, W. H. Holmes; *General Secretary*, Hannah L. Bartlett; *Treasurer*, Perry B. Pierce; *Curator*, Mariana P. Seaman; *Councilors-at-large*, Alice C. Fletcher, J. Walter Fewkes, and J. D. McGuire. At the ensuing meeting of the Board of Managers the councilors were increased by the election of Weston Flint, F. W. Hodge, Walter Hough, George M. Kober, D. S. Lamb, John H. McCormick, Edith C. Westcott and Thomas Wilson; and the organization was completed by selecting Walter Hough as Secretary to the Board, and designating the vice-presidencies as follows: Somatology, D. S. Lamb; psychology, Frank Baker; esthetology, W J McGee; technology, J. Walter Fewkes; sociology, George M. Kober; philology, J. W. Powell; sophiology, Alice C. Fletcher.

At the annual meeting of the Columbia Historical Society, held on January 7, 1901, officers for the ensuing year were elected as follows: *President*, John A. Kasson; *First Vice-President*, Ainsworth R. Spofford; *Second Vice-President*, A. B. Hagner; *Treasurer*, J. Dudley Morgan; *Recording Secretary*, Mary Stevens Beall; *Corresponding Secretary*, M. I. Weller; *Curator*, James F. Hood; *Chronicler*, William B. Bryan; *Managers* (for term expiring in 1905), Lewis J. Davis and J. Ormond Wilson.

It will be remembered that at the fourth International Zoological Congress, held at Cambridge in 1898, it was decided that the fifth Congress, in 1901, should be held in Germany. Announcement has now been made, says *Nature*, that the meeting place will be Berlin, on August 12–16, and the president, Professor K. Moebius, director of the zoological collection of the Natural History Museum, with Professor F. E. Schulze, director of the Zoological Institute, as vice-president. The secretaries of the Congress will be Herr P. Matschie, Dr. M. Meissner and Dr. R. Hartmeyer. The treasurers will be Herr H. Schalow and Herr Otto Stutzbach. Arrangements as to meetings and papers will be in charge of Professor L. H. Plate; apartments and receptions will be under the care of Dr. L. Heck, and the lighter pleasures of the meeting will be managed by Dr. O. Jaekel. The meetings will be held in the Natural History Museum and neighboring rooms of the University. Among the subjects to be brought before the Congress are the following: 'Fossil Remains of Man,' Professor Branco (Berlin); 'Vitalism and Mechanism,' Professor Bütschli (Heidelberg); 'Theories of Fertilization,' Professor Yves Delage (Paris); 'The Psychological Attributes of Ants,' Professor A. Forel (Morges); 'The Malarial Problem from a Zoological Point of View,' Professor Grassi (Rome); 'Mimicry and Natural Selection,' Professor E. B. Poulton (Oxford). After the conclusion of the Congress an excursion will be made to Hamburg for the purpose of visiting the Natural History Museum and Zoological Garden there, and also to Heligoland. Communications concerning the Congress should be made to the president, 43, Invalidenstrasse, Berlin, N. 4. Admission to the Congress will be free to all zoologists and all friends of zoology.

It is stated in *Terrestrial Magnetism* that the Magnetic Observatory at Cheltenham, Mary-

land, near Washington, D. C., which is to form the principal base station of the magnetic survey of the United States, is now ready for the installation of the instruments. The buildings were constructed under the superintendency of Mr. J. A. Fleming, of the Coast and Geodetic Survey, who also drew up the plans. Dr. W. G. Cady, a graduate of Brown University, and of the University of Berlin, and a member of the Division of Terrestrial Magnetism during the past six months, will have principal charge of the observational work. It is the intention to carry out at this observatory magnetic, meteorological, seismological, atmospheric-electric, and earth current observations.

AT the meeting of the New York Zoological Society on January 15th the following officers were reelected: *President*, Levi P. Morton; *Executive Committee*, Levi P. Morton, *ex-officio;* Henry F. Osborn, chairman; John L. Cadwalader, counsel; Charles T. Barney, John S. Barnes, Philip Schuyler, Madison Grant and William White Niles. The report of the Executive Committee sets forth the necessity for an increase of annual membership to 3,000. The income is now $7,900 annually, and what is needed is an income of $30,000 annually. The report speaks of the increasing attendance, and says that with the additional increase from rapid transit the walks, paths and buildings will be taxed to their utmost. The total attendance for the year was 325,925. Regarding the funds appropriated by the city for maintenance of the park, the report has this to say: "For two years there has been a deficiency in maintenance, owing to no lack of good will on the part of the city authorities, but a failure to appreciate the needs of the Park. In 1899 the City contributed $30,000 and the Society contributed $7,038.61 towards the maintenance of the Park. In 1900 the maintenance fund of $40,000 again resulted in a serious deficiency, which has been met by the Society by a contribution of $6,524.04. The Society estimated $80,000 as the fund needed for 1901, in order to meet the increased demand for food and additional keepers; the fund assigned is $65,000. We trust that this fund will enable the committee by the greatest economy to maintain the Park on its present limited scale without a serious deficiency.

MR. CARNEGIE has offered to build at Syracuse a library for $200,000. The city will provide a site and $30,000 for maintenance.

THE new building for the Boston Medical Library was formally opened on January 12th. The speakers announced on the program were: Dr. Francis W. Draper, president of the Massachusetts Medical Society; Dr. William Osler, professor of medicine in Johns Hopkins University; Dr. John S. Billings, librarian of the New York Public Library; Dr. Horatio C. Wood, of the University of Pennsylvania, and Dr. Henry P. Walcott, acting president of Harvard University. The new building, which is on the Fenway, is of stone and brick, and contains ample accommodation for the library of 32,000 volumes, together with rooms for lectures and meetings.

THE Swiss Parliament has voted a permanent subsidy to the Concillium Bibliographicum, which assures the continuation of the work inaugurated and carried forward with so much energy by Dr. H. H. Field. The vote was passed without opposition in the lower house and nearly unanimously in the upper house.

THE executive board of the Association for maintaining the American Women's Table at the Zoological Station at Naples and for promoting Scientific Research by Women announces that, in addition to maintaining a table at Naples, it is able to offer for the season 1901 the free use of a table at the Marine Biological Laboratory at Wood's Holl. The appointments are made by the executive board, with the cooperation of a regularly appointed board of advisors, on whose judgment the executive committee relies for decision in questions relating to the scholarship of candidates based on the results of work presented for examination. The members of the present board of advisors are Professor Ethan A. Andrews, of Johns Hopkins University, Professor R. H. Chittenden, of Yale University, and Dr. W. T. Porter, of the Harvard Medical School. The year of the Association begins in April, and all applications for the year 1901, both for the table at Naples and for that at Wood's Holl,

should be sent, on or before March 1, 1901, to the secretary, Miss Florence M. Cushing, 8 Walnut street, Boston, Mass.

As we have already announced the same Association has offered a prize of one thousand dollars for the best thesis presented by a woman, on a scientific subject, embodying the results of her independent laboratory research in any part of the field covered by the biological, chemical and physical sciences. The board of examiners for the prize is as follows:

Biological Sciences: Dr. William H. Howell, Johns Hopkins Medical School; Dr. William Trelease, Washington University; Dr. Charles O. Whitman, University of Chicago; Dr. Edmund B. Wilson, Columbia University.

Chemical Sciences: Dr. Russell H. Chittenden, Yale University; Dr. John U. Nef, University of Chicago; Dr. Ira Remsen, Johns Hopkins University: Dr. Theodore W. Richards, Harvard University.

Physical Sciences: Dr. Carl Barus, Brown University; Dr. Albert A. Michelson, University of Chicago; Dr. Edward W. Morley, Western Reserve University; Dr. Arthur G. Webster, Clark University.

THE International Mining Congress will meet at Boise, Idaho, in July of the present year.

ACCORDING to a recent bulletin of the Census Bureau, the center of population of the United States is now latitude 39.9.36; longitude, 85.48.54, having moved westward about fourteen miles and southward about three miles since the last census.

THE *British Medical Journal* states that Professor Claudio Fermi and Dr. Tonsini, of Sassari, have recently reported the results of experiments in the prophylaxis of malaria made by them in the island of Asinara, off the northwest coast of Sardinia. They succeeded in destroying the *Anopheles* larvæ by means of petroleum poured into the pools of the island. This was repeated twice a month. The process was begun in June and continued until the end of November. The mosquitoes in the air were destroyed inside houses by means of a mixture of powdered pyrethrum, chrysanthemum, valerian, etc., and the *zanzolina* of Celli and Casagrandi. In the dormitories of prisons, when there was nothing better available, chlorine, generated by treating calcium chloride with sulphuric acid, was employed. Protective nettings were applied to windows. The result was that hardly any *Anopheles* were found in any dwelling, while *Culex pipiens* was much scarcer than in former years. Not a single case of primary malaria was observed.

THE Wisconsin Geological and Natural History Survey has in press two bulletins of its economic series. One of these is the first part of a report on the clays and clay industries of the State and is by Dr. E. R. Buckley, assistant superintendent of the Survey. The other, written by Professor U. S. Grant of Northwestern University, deals with the copper-bearing rocks of the northern part of the State. It is expected that these bulletins will be issued in January, 1901.

WE quote the following editorial note from *Nature*: "A few weeks ago the new anthropological collections in the American Museum of Natural History in New York were opened to the public, and these valuable collections now occupy five halls, and others are being provided. We learn from our contemporary, SCIENCE, that the accessions to the anthropological collections of the museum obtained during the last three years have largely been due to extended scientific research undertaken by the institution. In this respect the methods of the American Museum of Natural History differ considerably from those pursued by a number of other institutions. It has not been the policy of the museum to accumulate rapidly and indiscriminately more or less valuable specimens collected on trading expeditions or purchased from dealers; but an endeavor has been made to build up representative collections and to obtain at the same time the fullest and most detailed information in regard to specimens, so that each addition to the exhibit of the museum can be made thoroughly instructive and will represent a material contribution to science. There is no doubt this is the best way to build up a museum, and it is to be deplored that the various museums of the British Islands do not follow the example so worthily set by this and other American museums. Our English method is rather to wait like a spider in its web in the hope that something will eventually be caught;

in the meanwhile, other institutions are intelligently collecting wholesale in diverse interesting regions, while we are content with occasional specimens which usually have no history, or at most a very imperfect one, and for these we often have to pay a stiff profit to a dealer."

THE New York *Times* lays stress on its announcement that the newspaper contains 'all the news that's fit to print.' Does the editor regard the following, taken from a recent issue as 'fit to print'?

"James Conroy, of 127 Hopkins Avenue, Jersey City, claims to have devised a system of springs and weights, which, operating as a balance, will run machinery without the aid of fuel, electricity, or any other motive power. The system is so simple, he says, that the only wonder about it is that it was never discovered before. It may be operated, he says, by a boy. While it is not perpetual motion, he says it will run until one of the springs or some other part of the arrangement breaks, but that will only mean a cessation of movement until a new part is substituted for that which is broken. He will not exhibit his machinery, but says he has demonstrated its power by operating a pump in his house. All he will say is that the power is furnished according to a decimal system making ten pounds the unit of weight. This unit may be increased by multiples of ten until the desired power for any machine is attained. He says he can easily satisfy any engineer of the validity of his claims. Another thing Mr. Conroy claims is that should any part of the machinery break the machine will not be wholly disabled, but will continue to run with a power diminished only by the broken part, which will be one-tenth, the diminution continuing in that ratio for each broken part."

THE Calcutta correspondent of the London *Times* cables that since the Pasteur Institute was opened at Kasauli about 100 patients bitten by mad dogs have been treated, among whom not a single death has occurred. Appeals for funds from the municipalities, however, have been rejected. Native opinion, especially among the Hindus, joins the Buddhists in pronouncing against the Institute owing to a mistaken idea that cruel operations are practised upon living dumb animals. Memorials have been submitted to the Government protesting against State aid, though this is only given to enable British soldiers to be treated in India instead of proceeding to Paris, thus saving a large sum annually. Bishop Welldon, preaching in the cathedral, referred to the opposition to the Institute in England and India. He said he had visited Kasauli and seen the operations, and stated that the medical process was characterized in all its aspects by the most thoughtful and scrupulous humanity. Anesthetics were employed, and the animals showed no visible sign of suffering, dying eventually, not of hydrophobia, but of paralysis. He urged people to be slow to condemn a remedial process which, at the cost of a slight infliction of pain on animals, relieved and removed suffering so intense as hydrophobia in the case of human beings.

THE report of the Meteorological Council of the Royal Society for the year ended March 31, 1900, has been issued. The work of the council is summarized under the heads of ocean meteorology, weather telegraphy and climatology. The inquiry relative to the unusually severe weather which prevailed in the Atlantic during the winter 1898–99 has been completed, and the charts illustrating the results of the investigations will be ready for publication shortly. A table is given comparing the forecasts for the United Kingdom with the subsequent weather actually experienced. The complete success, partial success, partial failure and complete failure of the forecasts are estimated according to definite rules. Partial success and partial failure are defined as meaning that the forecast was correct or incorrect for more than half the elements dealt with at the places of observation situated in the district in question. This table, when summarized, gives 55 per cent. of complete successes, 27 per cent. of partial successes, 12 per cent. of partial failures and 6 per cent. of complete failures.

UNIVERSITY AND EDUCATIONAL NEWS.

THE following large gifts for education have been made during the week: John D. Archbold of New York City, a vice-president of the Standard Oil Company, has given $400,000 to the endowment fund of Syracuse University, on the condition that a like amount be raised among other friends of the institution; Mr. Andrew Carnegie has given $225,000 to the

Upper Iowa University, at Fayette, Ia., to be used preferably for a library, and $50,000 to Aurora College, an Illinois institution; Augustana College at Rock Island, Ill., has received about $30,000 from Messrs. E. C. and J. A. Ericsson, of Boone, Ia.; Mr. John D. Rockefeller has offered to give $15,000 to Carson and Newman College, a Baptist institution in Tennessee, provided $50,000 in addition be raised; Carleton College, at Northfield, Minn., has added $150,000 to its permanent endowment fund, $50,000 being the gift of Dr. D. K. Pearsons, and the remaining $100,000 being raised from various sources.

GIFTS to educational institutions in Great Britain include the following: Mr. Charles W. Mitchell, £20,000 to the University of Aberdeen to pay the debt of the University; Lord Durham, £1,000 towards the building fund of the Durham College of Science, and the Misses Mercer, £1,000 to establish a scholarship, or scholarships, in chemistry at the Blackburn Technical School in memory of the late Mr. John Mercer, the discoverer of the process of Mercerized yarn.

THE registration at Harvard University, as recorded in the issue of December 21st last of this journal, appears to need correction. Professor Storer calls our attention to the fact that the figures for the Bussey Institute and for the veterinary school were not included. These should be 33 and 18 respectively. On the other hand, the registration of the Medical School is too large. Dean Richardson, of the Medical School has explained the matter as follows: "Mr. Cram must have misunderstood your question and gave you the number enrolled, which at that time was 600, and added to it the number which were enrolled in the summer courses, 149, making a total of 749."

THE President of the Board of Education, London, has appointed a committee, consisting of Sir William de W. Abney, K.C.B., F.R.S. (Chairman), Sir Philip Magnus, Sir Swire Smith, Mr. G. R. Redgrave, Mr. W. Bousfield, Mr. W. Vibart Dixon, with Mr. A. E. Cooper, Board of Education, South Kensington, as Secretary, to consider the best means for coordinating the technological work of the Board of Education with that at present carried on by other educational organizations.

A CABLE despatch from St. Petersburg reports that one hundred and fifty students, recently arrested at Kieff for engaging in political agitation, are to be expatriated to Port Arthur, where they will do military service. The same fate awaits scores of students arrested at the capital on a similar charge. The ferment continues among students throughout the country, and disturbances are anticipated. The troubles at Kieff do not seem to have been due to political agitation but to the unwillingness of the students to attend the lectures of an unpopular professor.

MR. H. V. CARPENTER, assistant in physics at the University of Illinois, has accepted an assistant professorship in physics and electrical engineering in the Washington Agricultural College, at Pullman, Washington. Mr. Carpenter is a graduate of the University of Illinois.

MR. U. S. HANNA, Harrison fellow in mathematics and astronomy of the University of Pennsylvania, has resigned his fellowship to resume his duties as instructor in mathematics at the University of Indiana.

MR. S. W. REAVES, graduate scholar in Cornell university, has been appointed instructor of mathematics in Orchard Lake Military Academy.

DR. F. MONTESER has been promoted to a professorship of mathematics in the School of Pedagogy, New York University.

MR. C. T. R. WILSON, F.R.S., fellow of Sidney Sussex College, Cambridge, has been appointed university lecturer in experimental physics in succession to Professor Wilberforce, who, it will be remembered, recently accepted a call to Liverpool.

DR. P. DRUDE, professor of physics in the University at Giessen, has been called to Tubingen. Dr. A. Voelzman, of Berlin, has been promoted to a professorship of zoology. Dr. A. Steur has qualified as docent in geology in the Technical Institute at Darmstadt, and Dr. George Wetzel for anatomy in the University at Berlin.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, FEBRUARY 1, 1901.

CONTENTS:

A Decade of North American Paleobotany: PROFESSOR D. P. PENHALLOW ... 161
Determination of the Sun's Distance from Observations of Eros: PROFESSOR W. W. CAMPBELL... 176
On the Nature of the Solar Corona, with some Suggestions for Work at the Next Total Eclipse: PROFESSOR R. W. WOOD ... 179
Chicago Section of the American Mathematical Society: PROFESSOR THOMAS F. HOLGATE ... 181
Wisconsin Academy of Sciences, Arts and Letters: FRANK CHAPMAN SHARP ... 181
Scientific Books:—
Ormond on the Foundations of Knowledge: PROFESSOR R. M. WENLEY. *Cohnheim's Chemie der Eiweisskörper:* PROFESSOR LAFAYETTE B. MENDEL. *Notter's Treatise on Hygiene:* DR. W. H. PARK ... 182
Scientific Journals and Articles ... 186
Societies and Academies:—
Geological Society of Washington: DR. F. L. RANSOME AND DAVID WHITE. *Biological Society of Washington:* F. A. LUCAS. *Philosophical Society of Washington:* CHARLES K. WEAD. *The Las Vegas Science Club:* T. D. A. C. *New York Section of the American Chemical Society:* DR. DURAND WOODMAN ... 187
Discussion and Correspondence:—
Note on Vegeto-electricity: I. THORNTON OSMOND. *Scientific Expedition to Iceland, Greenland and Labrador:* DR. R. A. DALY ... 191
Current Notes on Meteorology:—
Report of the Chief of the Weather Bureau; West Indian Hurricanes; The Monthly Weather Review: PROFESSOR R. DEC. WARD ... 192
Botanical Notes:—
Botanical Opportunities in Washington; Central Massachusetts Forests; Chrysanthemum Rust: PROFESSOR CHARLES E. BESSEY ... 193
The National Observatory Question ... 195
Scientific Notes and News ... 196
University and Educational News ... 199

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

*A DECADE OF NORTH AMERICAN PALEOBOTANY. 1890–1900.**

THE history of paleobotany constitutes a record of the most persistent and painstaking efforts to unravel a series of great facts which have been left by the wayside of time through an untold period of the earth's history, and to interpret them with reference to their true significance in the life of this planet.

Although attention had been directed to the phenomena of plants preserved in the crust of the earth essentially with the first discovery of coal, their occurrence did not excite very marked interest until the latter part of the seventeenth century—the observations of that time being made from the standpoint of the curious in nature, rather than from an appreciation or even suggestion of their scientific value, and it was not until 1709 that the first meritorious attempt to describe them in a scientific spirit was made. From then on through the remainder of the eighteenth century, a very considerable literature accumulated, and the infant science passed through what Ward has so very aptly called the 'twilight of its development,' while very nearly a full century passed before Schlotheim published the results of those studies which must be taken

* Address of the President of the Society of Plant Morphology and Physiology, given before the Baltimore Meeting, December, 1900.

as the real commencement of paleobotanical investigation. His work gains special prominence by reason of his having been the first to definitely and authoritatively deny the deluge theory and to assert that fossil plants represent the remains of an earlier vegetation, the originals of which are no longer to be found. But it was not until the time of Sternberg and Brongniart, of Lindley and Hutton, of Witham and of Göppert from two to three decades later, that interest in this line of research gained sufficient impetus to make its continuity assured. From that time on, progress has advanced at an accelerating rate, but the one fact which we need to keep clearly before us is that such progress as has been made in this branch of botanical science has been accomplished within the last seventy years. The activity thus referred to was chiefly confined to Europe, at least during the first half of the century, but it is of value to note that the great interest in such work, which centered there, in all probability had a well-defined influence upon the same line of studies in America—indeed, we may almost say a determining influence in promoting that spirit of enthusiasm for a subject then surrounded with the greatest difficulties, which has led to such noteworthy results. It is at least a fact of more than passing interest that the two earliest among the great paleobotanists of this continent—Dawson and Lesquereux—entered upon their work here just before the completion of the first half-century, and it seems not unlikely that while the one had imbibed a strong predilection for such studies from those eminent geologists with whom he had been associated while a student at Edinburgh, the other had gained inspiration not only from his scientific associates at Neuchatel, but also from the success of his earlier efforts as a botanist and his special studies of peat bogs for which he received the government medal, and through which also, he gained wide celebrity. It was, therefore, but natural that in returning to his native land to follow out the ideas so well established in Europe, Dr. Dawson should at once apply himself to the solution of the many problems which the rich deposits of fossil plants in the neighborhood of his own home at once suggested; and that Lesquereux, seeking in the United States an asylum from the political troubles which drove him and his colleagues from Switzerland, should at once continue there those studies which had already brought renown, and, in the rich deposits of Pennsylvania, Ohio and other States, endeavor to read the story of the ages as inscribed in the rocks of the Carboniferous formation. These facts are of significance in considering the progress of paleobotanical work on this side of the Atlantic, since Dawson and Lesquereux, the one in Canada and the other in the United States, were its most powerful exponents. Newberry was born and educated in the States, so that his activity in this direction was the result of purely local conditions. He, nevertheless, contributed most important results, chiefly in connection with public surveys, and his name stands with those of Dawson and Lesquereux as foremost among the paleobotanists of this continent. It is impossible to consider any progress in this subject, either now or in the immediate past, without reference to their work, since it stands as the foundation of that from which some of our most important deductions may be derived.

Lesquereux died on the 25th of October, 1889; Newberry died on the 7th of December, 1892, while Dawson died on the 19th of November, 1899, and thus within the short space of a decade there passed from our midst three of the most notable of the scientific men of this continent. I have felt it to be of special importance to give prominence to these names, since they stand

as the great link which binds the old to the new. As they commenced their work under conditions which are unknown to-day, they completed it with a full recognition of the different point of view which had been introduced by the wonderful progress of botanical science in recent years, and their final publications fell within the closing decade of the century. With the disappearance of these three men whose great activity accomplished so much, we now turn to the Smithsonian Institution and the United States Geological Survey, with their superb resources in material, appliances, and a well-trained staff of scientific men, as the real center of our future progress.

The somewhat peculiar conditions surrounding the study of fossil plants in the earlier days of the subject somewhat naturally led to its exploitation by geologists into whose hands it fell, and where it has very largely remained until the present day. There has thus arisen a somewhat prevalent idea that the study of fossil plants constitutes a science altogether apart from that of botany, and for this state of affairs the botanists are themselves chiefly to blame for not promptly claiming and cultivating a field peculiarly their own, for, as Ward well observes, "Botanists have, as a rule, ignored paleontology, while the paleontologists have gone on with their classifications in total disregard of the former." And he very appropriately adds that "The mutual dependence of these two branches of botanical science upon each other is so apparent that it is certainly a matter of surprise that it has received so little recognition by scientific men."

In whatever conditions this state of affairs may have had its origin, it is certainly gratifying to observe that botanists generally are more keenly appreciative of the valuable nature of the evidence which fossil plants may afford in solving questions of descent. It is also encouraging to discover that history does not fully sustain the extreme charge which has been brought against the botanical profession. Accepting Ward's list of twenty-two men from Scheuchzer to Carruthers, who may be considered to constitute the world's great leaders in paleobotanical research, it is to be noted that fifty per cent. were especially trained and exercised their profession as botanists—there being among the number those who have produced a strong impress upon the general history of the science, and it will well repay us to briefly glance at some of their achievements.

In 1820 Sternberg commenced the issue of his well-known *Flora der Vorwelt*, the publication of which extended over a period of eighteen years. This important work, together with the succeeding works of Brongniart, Göppert and Corda, opened the way for the final reception of the idea of evolution in plants.

To Adolph T. Brongniart, a contemporary of Sternberg's, must be ascribed the greatest measure of influence exerted upon the development of paleobotany during the first three decades of the century,—a fact so eminently true that he is commonly spoken of as the real founder of the science. His observations upon the formation of pollen grains in the mother cells of *Cobœa*, and the frequency of occurrence of the pollen tube, were the first to direct attention to this new line of inquiry. In 1843 he devised and published a system of classification which not only maintained a strong hold in France for many years, but it gained many adherents throughout Europe. In his work on fossil plants we gain, for the first time, a definite indication of that succession in the development of plant life through the various geological formations, which constitutes so important a feature of modern botanical science.

Göppert was the first to draw attention

to a rise in temperature during the process of germination, and his works on fossil plants are too extensive and well known to require special consideration at this time; but in the prosecution of his studies, he strongly emphasized the necessity of treating all such remains from a strictly botanical point of view, and he was especially prominent in giving great weight to characters derived from a study of the internal structure, thus recognizing the school already founded by Witham in England.

Corda was already well known for his valuable work on the fungi and mosses, before entering upon those paleobotanical studies through which his name more commonly appears.

The great number and value of Unger's contributions to botanical science lent special weight to his conclusions respecting fossil plants. In 1837 he described the spermatoids in various mosses and declared them to be the male elements of fertilization. In 1855 he first directed attention to the great resemblance between the protoplasm of the plant cell and the sarcode of the more simple animals,—a discovery which was later brought into great prominence and finally led to the conclusion that protoplasm is the foundation of all organic development. He was the first to successfully oppose Schleiden's theory of free cell formation as applied to the growing apex of stems, and to show that such cells arise by division—having their origin in a meristem. His work, in conjunction with that of von Mohl, Nägeli, Braun and Hofmeister, laid the foundation for a true conception of cell formation. In his 'Anatomie und Physiologie der Pflanzen' he introduced many new and valuable ideas respecting the character of the protoplasm, and gave a concise idea of the cell in its various complexes as families, tissues and fusions. With von Mohl's text-book, this work accomplished more than any other in disseminating a knowledge of the subject up to 1860. In 1850 he issued the first complete manual of fossil plants, giving a systematic account of 2,421 species.

C. F. Schimper founded the theory of phyllotaxis. He first contributed to the study of fossil plants in 1840, and his 'Traité de paléontologie végétale' constitutes the most important of all the works on fossil botany as presenting a complete manual of the subject in accordance with the then current ideas of botanical science.

Williamson has contributed to the advance of paleobotanical knowledge in so many important ways, especially during his later years in conjunction with Carruthers, that a preliminary statement of progress would be wholly incomplete without reference to his work. His earliest experiences were gained in making the illustrations for 'Lindley and Hutton's Fossil Flora of Great Britain in 1837.' Since then his time was largely devoted to independent research in the same field, with a success which is well known, and his studies of the carboniferous flora of Great Britain have resulted in most important contributions to our knowledge of those early types of vegetation. This is especially true with respect to the Calamarieae, Lepidodendreae, Sphenophylleae, the ferns and Lyginodendron. In the case of the first two, more particularly, he laid the foundation for all our subsequent knowledge respecting them. He furthermore showed that in Lyginodendron the fructification places this group of plants beyond question among the archegoniates, but that like recent Gymnosperms, they possess a secondary wood growth from a cambium layer. In establishing this fact he came into direct contact with the views of Brongniart, who held the formation of the wood from a cambium layer to be an absolute criterion of the phanerogams. From Heterangium and Lyginodendron he reconstructed a type of plant which he de-

scribed as having characters intermediate between those of the ferns and the Gymnosperms, and he thus opened the way for the final recognition of the Cycadofilices by Potonié, to which also such hitherto doubtful types as Medullosa and Myelopteris undoubtedly belong—a group of plants the recognition of which has gone far toward clearing up most important questions relating to the phylogeny of the Gymnosperms, and of the Cycads in particular.

It will thus be seen that to a large extent at least the study of fossil plants has proceeded on lines parallel with those in other branches of botanical science, and that the growth of the subject has substantially been directed by men eminent as botanists. Originally employed as a distinctive term for a subject supposedly outside of botanical science, paleobotany has more recently come to have equal rank with other divisions of the science such as histology, physiology, ecology, etc. Such artificial distinctions as formerly existed are fast disappearing, and we are now rapidly approaching, if we have not already entered upon, the first stages in the realization of that harmony between the botany of recent and extinct forms, the accomplishment of which Ward in 1885 recognized as so eminently desirable, but considered so difficult of attainment.

One of the earliest views attaching to the relations of paleobotany and geology was that of the supposed value of fossil plants in determining the age of deposits, and this found expression in the idea that the sequence with which plants were known to occur must be correlated with the succession of geological formations in such a way that the age of the latter could be ascertained by an examination of the flora. Although fundamentally correct, the precise application of the principle was found to lead to such erroneous conclusions that geologists soon came to look upon the evidence of fossil plants as untrustworthy, and it is only within recent years that there has been any material alteration in this point of view. So long ago as 1871, however, we find Sir William Dawson, who possessed a deeper insight into the bearings of evidence derived from fossil plants than was the case with the majority of geologists, expressing the opinion that "fossil plants have hitherto been regarded as of much less importance than fossil animals in determining the age of rocks, and in some portions of the geological series, where formations are strictly marine, their value is, no doubt, quite subordinate. But there are portions of the geological formations * * * in which their value becomes much greater"; and in 1892 we find him giving a more pronounced expression of opinion when he says that "The history of geological discovery in the Canadian Northwest affords a convincing proof of the value of fossil plants when carefully collected, * * * in determining the geological ages of the formations in which they occur, while there can be no question of their paramount value in indicating geographical and climatal conditions."

In 1882, Ward laid down in a definite and authoritative manner, the principles of geological correlation by means of fossil plants. He clearly showed that the old idea of contemporaneous deposits with identical fossils, as originally stated with so much prominence by Schimper and others, is entirely erroneous, and that it is relative contemporaneity or correspondence of succession which must be considered, an idea which the late Sir William Dawson often laid great stress upon in the course of his discussions with the writer. In order to give proper expression to the idea of correspondence of succession, Ward has proposed and for several years has employed the appropriate term 'homotaxis.' He lays down the general principles that

1. Great types of vegetation are characteristic of the great epochs in geology, and it is impossible for types of one epoch to occur in another.

2. Given a sufficient body of facts—*i. e.*, a suitable series of specimens—it is possible to determine as conclusively for nearly related deposits as for those more widely separated.

3. It is of the highest importance that plants should be correctly determined.

At the same time White, who deplores the 'surprising and painful inadequacy of materials relating to stratigraphic paleobotany,' shows that the present temporary obstacles to accuracy in correlation are to be found in

1. The wide vertical range of identical species.

2. The lack of standard paleobotanic sections, *i. e.*, a knowledge of plants strictly limited to various beds.

These principles form the basis of methods which have been used for the last eight years, and are employed with great success by members of the United States Geological Survey in determining the ages of deposits. This practise finds one of its latest and best expressions in a paper by Mr. David White on the 'Relative Ages of the Kanawha and Allegheny Series.' On account of similarity in the material composing it, the similar position of the series as a whole in the general lithological sequence, and the fact that the Allegheny series has been traced stratigraphically with great detail as far as central West Virginia, the Kanawha series has long been regarded as *in toto* the exact, though greatly expanded, equivalent of the Allegheny series. Following out the methods formulated by Ward, White has conclusively shown that this view is not a tenable one, but that as indicated by the testimony of the fossil plants, only the upper half of the Kanawha series can be correlated with the lower portion of the Allegheny series, in each of which identical forms of plants occur; whence it appears that the two series overlap in such a manner that the Allegheny is in direct chronological succession in the lower Kanawha.

The occurrence of plant remains in the coal measures, which were in their general features comparable with existing types in the tropics, led Schlotheim to regard fossil plants as having a direct value in determining the nature of the climatic conditions under which they flourished. This idea was later taken up by Brongniart, who amplified it, and from the various types of vegetation known by their fossil remains, determined what he conceived to be the climatic conditions of the great geological periods, corresponding to the great changes in plant types. The views thus adopted have been accepted in principle by all succeeding authorities and constitute our guide post to day. Writing in 1879, the late Asa Gray felt no hesitation in laying down the general rule that "Plants are the thermometers of the ages, by which climatic extremes and climates in general through long periods are best measured," and in this connection he also pointed out that "Even very moderate changes either one way or the other, in temperature, would have excluded either the vine or the date palm which for at least five or six thousand years, have grown in proximity and furnished food to the inhabitants of the warmer shores of the Mediterranean." Three years later, in the course of extending his important studies relative to the Erian and Upper Silurian formations, Sir William Dawson laid down the general rule that "When we can obtain definite information as to the successive floras of any region, we thereby learn much as to climate and vicissitudes in regard to the extent of land and water," and that with reference to such points, "The evidence of fossil

plants, when properly studied, is, from the close relation of plants to their stations and climates, even more valuable than that of animals." But he very appropriately adds the caution that "In pursuing such inquiries, we should have some definite views as to the nature and permanence of specific forms, whether with reference to a single geological period or to successive periods."

Balfour had already pointed out the necessity for a wide acquaintance with plant distribution in order to apply fossil plants with any success as tests of climate, and Renault in 1881, expressed views similar to those held by Dawson, when he pointed out that plants were superior to animals as a test of climate because of their relative fixity, and therefore more permanent relations to their environing conditions—the ability to migrate rendering animals an uncertain guide.

While their relative fixity is an element which imparts a special value to plants in this respect, it must nevertheless be recognized that influences such as long rivers with a northerly and southerly course, are likely to introduce a disturbing element by reason of their causing a mingling of the floras of dissimilar climates, and for this and other reasons it is generally conceded that drift material must be carefully excluded from all considerations which involve questions of climate.

Variations in the soil, exposure to light, humidity of the atmosphere and many other conditions which tend to promote structural and functional modifications, and eventually also type alterations, must be carefully weighed and that these elements have been as important factors in the past, as they are at the present day, cannot be doubted when we recall the profound modifications exhibited by the various floras of Paleozoic time, and the fact, to which Lesquereux has directed attention, that "A single modification of the character of the vegetation generally follows great geological disturbances which produce permanent changes in the atmospheric condition of a country."

In 1872 Saporta pointed to the determining influence of atmospheric conditions, and showed that the relative preponderance of the monocotyledons and dicotyledons could be referred to conditions of humidity in such a way that the former increase while the latter decrease when the humidity becomes general, or with a diminution of temperature; and that, in consequence, a dry and warm climate favors a larger proportion of dicotyledons than a warm and moist, or a cold and moist climate. With these considerations in mind, we cannot avoid the conviction that the modern science of ecology as expounded by Warming and Schimper, and as exploited on this side of the Atlantic by Ganong and others, must throw much light upon questions of this kind by giving accurate data upon which to base comparative studies.

The peculiar conditions under which plants pass into the fossil state render it an altogether exceptional circumstance to find all parts present. This is more particularly true of those more delicate tissues and organs which constitute the structure of the gametophyte, but it also applies with considerable force to all the soft parts of the sporophyte. Important exceptions to this rule nevertheless appear. Renault has already shown that in Cordaianthus, the microspores are to be seen in position within the canal of the archegonium, as also in the pollen chamber, and they exhibit very clearly the development of the prothallus. He has also observed similar conditions of preservation in various Calamarieae. More recent investigations have also given another important example of this kind in *Parka decipiens*, the remains of which show prothalli and both kinds of spores, and, coming as it does from the Devonian, it

probably stands as the most ancient representative of the heterosporous filicineæ we know. Other less conspicuous cases might also be cited, but the general fact that it is only the more resisting structures, such as those of the stem and leaves, which are recognizable, has led to attaching great importance to the anatomy of the wood. This was first pointed out by Witham, who has since been followed by many of the leading paleobotanists of Europe, and to some extent by those of America. On this side of the Atlantic, the idea was first taken up by the late Sir William Dawson in 1845, and since that time its application has been made more prominent through the work of Knowlton and others.

As a special indication of climate, the presence of growth rings—from the time of Witham who considered the absence of such structural features to be evidence of a tropical climate—has been regarded as one of the important factors in this respect. The history of the subject shows a great divergence of opinion as to the origin of these structures, but the general position may no doubt be correctly taken, that growth rings are largely dependent upon, and are therefore expressive of alternating periods of growth and rest. Such periodicity in functional activity bears a more or less close relation, among other things, to seasonal change in such a way that, other things being equal, the more definite the changes from summer to winter, the more pronounced will the growth rings become, and the more definite will be their correspondence with age. That this holds true only within certain limits is well known. Thus many Chenopodiaceous plants make several growth rings within one season independently of latitude, and the red maple, within the latitude of New York State, has been known to make twelve growth rings within a period of eight years. Fernow has recently drawn attention to the fallacy of many of the opinions respecting the value of growth rings as an index of age, and the correctness of the views which hold them to be of importance in this respect, and he points out that under ordinary circumstances in temperate latitudes the ages of trees may be correctly ascertained within a limit of one-half to one year of error. Tropical trees generally exhibit an absence of growth rings, but exceptions to this rule are not unknown. It would therefore appear that while much caution must be exercised in applying such a test to the case of fossil plants, when used with a due recognition of its limitations, the test of growth rings as evidence of climate becomes a valuable aid.

One of the most common methods of identifying fossil plants has been through their leaves. This has of necessity resulted from the fact that these organs are much better adapted to preservation than most other parts of the plant, and that they therefore constitute the most accessible of all plant remains. The work of Lesquereux and Newberry rests very largely, indeed almost exclusively, upon evidence of this sort, and the venation has been made the basis of both generic and specific distinctions. Leaves, however, offer an unreliable basis when taken alone, and this results from the fact that the venation is not of specific rank, and often fails also in generic significance, while the form of the leaf may present so many changes within the limits of the species that no great dependence can be placed upon it. This is notably the case in such genera as *Liriodendron*, *Sassafras* and *Platanus*, and it is only necessary to refer to the comparative studies by Ward, on the 'Paleontologic History of the Genus *Platanus*,' and to the observations of Holm on Liriodendron, to give emphasis to facts long known to botanists, and show what erroneous and extremely misleading results may readily follow from the study of fossil

leaves, even when they are presented in a complete condition—a difficulty which is enormously increased when the fossil happens to be fragmentary, as is generally the case. The errors arising from a disregard of such facts, have led to no end of confusion, and have been among the most prolific causes of extensive revisions. It is therefore clear that for botanical purposes such fragments have a very limited value, but as Ward very correctly observes, for geological purposes it is not so much a question of correct botanical determination as the correct recognition of a plant once named and associated with a given deposit. With these limitations before us, we can form a more correct estimate of some of the recent conclusions bearing upon the climatology of former geological times.

The great analogy of climatic conditions recognized as existing between those which influenced the flora of the Dakota Group and those which now govern the vegetation of the North American continent, led Lesquereux to the conclusion that the flora of North America is not at the present epoch, and has not been in past geological times, composed of foreign elements brought to this continent by migration, but that it is indigenous. Its types are native, and the diversity of their representatives has been produced by physical influences. All the plants of the American Cenomanian, except those of *Ficus* and the *Cycads*, might find a congenial climate in the United States between latitudes 30° and 40°.

An examination of the Tertiary flora of the Yellowstone has shown that the present flora of the Park has comparatively little relation to it and cannot be regarded as a descendant of it. Knowlton concludes that the former had its origin to the south, while the latter had its origin to the north, and that the climate prevailing in Tertiary times was, therefore, quite different from that now known, and in all probability not unlike that of Virginia of to-day.

A study of the Lower Carboniferous Measures of Missouri has led Mr. David White to draw attention to the uniformity of climate which prevailed over Europe, within the Arctic Circle, in North America, Asia and, to some extent at least, in the southern hemisphere during Carboniferous times, and the probability that the extremely close relationship between the floras of the Culm, Millstone Grit and basal portions of the Lower Coal Measures in Europe and America point to wonderful facilities for plant distribution during Culm and early Mesocarboniferous time, facilities which, with the aid of an even climate, made possible the comparatively regular distribution and sequential order of probably nineteen-twentieths of the genera, and an unknown proportion of the identical species ; and he is disposed to consider that the conditions favorable to plant distribution, and consequent comparatively homogeneous dispersion of the successive floras of the Northern Hemisphere during the period extending from the later Culm to near the middle of the Mesocarboniferous, have never been equalled since. That there was plant migration cannot for a moment be doubted. Yet the evidence of distribution, of vertical range, of characteristic associations, and of the succession of the floras, indicate such geographical uniformity of climate and such facility of intermigration over a minimum distance, as to justify us in regarding the astonishingly similar associations of identical or closely related genera and species which characterize each stage, zone or group of the Culm and Mesocarboniferous, as essentially contemporaneous in all the basins of the Northern Hemisphere. From this evidence he draws the final inference that many of the species or genera of the Mesocarboniferous were, under local conditions, evolved

in different portions of the land surface, whence they spread with a rapidity difficult to conceive at the present day, over the greater portion of the northern continents.

An extended study of the Pottsville series of West Virginia offers an important illustration of the rapid differentiation of, and change in, floras during this period. White shows that "The period of change in conditions of environment attending transition from Lower Carboniferous marine to true Coal Measures formation, was marked by an extraordinarily rapid development and modification of plant species. Within a relatively short period the meager flora of the Devonian and Pocono is multiplied to the inexhaustively fecund and highly diversified flora of the Carboniferous, a development scarcely possible except in this division of organic life (plants), which is the most sensitive to climatic change or environment, excepting, perhaps, the higher vertebrates. In the lower part of the Pottsville series many species show a relation to the floras of the Vespertine or Calciferous Sandstone series; in the middle portion many of the forms are unique, while in thickly developed sections it is only near the top of the series that we see occasional Coal Measures forms creeping in."

Recent investigations, by the Committee of the British Association charged with an investigation of the Pleistocene deposits in the vicinity of Toronto, have brought out in a very convincing manner the fact that three distinct climatic periods may be recognized. During the first the vegetation and the climate were comparable with those now found in Labrador and the more northern portions of the Province of Quebec. This was followed by a period during which more southern types of vegetation were introduced, and the climate was probably comparable with that now common to the Middle United States. A third wave drove these plants southward again, and once more northern types of vegetation were introduced, but not quite so boreal in their character as the first, and these conditions have remained unchanged in the present day.

From the considerations which have thus been passed rapidly in review, it would appear that the advantage which such studies offer to the botanist is not very large, and that while the value of paleobotany to the geologist may, upon these grounds, be conceded to be great, the solution of questions bearing upon climate and geological succession can only be regarded as of a secondary importance from a botanist's point of view. The great problems which confront the botanist of to-day relate to the filling in of those gaps in plant descent which become apparent from a study of existing species. He is, therefore, called upon to complete, as fully as possible, our knowledge of that sequence in development which is at present justified, not only on theoretical grounds, but also on the basis of observed facts. To this end all other branches of the subject are subordinate, and since paleobotany has already contributed in so many important ways to enlarge our knowledge in this direction, it is my purpose to ascertain how far the progress of the subject in America, during the last decade, has proved of real assistance, the directions in which aid may be looked for, and the limitations within which useful results may be expected.

Our conception of the four great primary divisions of the plant world and of their subordinate branches is based upon the theory of succession in development, but our knowledge in this respect is far from complete, and here and there gaps occur in places where, on theoretical grounds, there should be perfect continuity in development. This defect arises from several causes.

The recognized law that the history of the individual more or less fully repeats the

history of the species, at once points to the superior importance of embryological data as the real link through which primitive forms may be united; but as we approach these primitive forms it is to be observed that the differentiation of types becomes less and less clearly defined until they merge in the ancestral form, and this must hold true of extinct types as well as of those now existing. While on the one hand such approximations may greatly aid in the solution of given problems, on the other they serve to defeat this end by reason of the difficulty experienced in their recognition and in a demarcation of their precise limitations.

In the progress of development many of the more primitive types of life have disappeared, while those of advanced organization have survived, and thus many of the gaps revealed by the study of existing species are of a more or less permanent character, and can only be bridged hypothetically. It is in emergencies of this kind that we instinctively turn to geological records, and in paleobotany seek the only available means of solving the difficulty. But here again, the complete obliteration of perishable material in the process of petrifaction, the breaking-up of the original body into widely separated fragments which can be correlated, if at all, only after the most prolonged and arduous labor, and the difficulty of recovering plant remains, even though they may be present in the rocks, constitute obstacles to the progress of knowledge in this direction, of the most formidable character. Hence from a botanical point of view, our knowledge is extremely imperfect; but when we take into consideration the serious nature of the difficulties involved, the substantial progress which has been made during the last seventy years, and more particularly during the last two decades, affords ground for much satisfaction.

In this connection we may note the somewhat suggestive observations of White to the effect that "The rapid development and series of changes or modifications, presented by the plants of the Pottsville Series of both Pennsylvania and West Virginia, point to the possibility that in this series we may eventually discover facts of the deepest significance relative to descent, but the present fragmentary nature of the material recovered, which consists altogether of portions of foliage, will not warrant final conclusions in this direction."

The relative sequence of the Pteridophytes and Spermatophytes, as also of the Gymnosperms and Angiosperms, the Monocotyledons and Dicotyledons as exhibited in geological succession, is substantially the same as that derived from the study of living forms. But with reference to their points of contact and the relations of the more subordinate divisions of these groups, especially with reference to the Thallophytes and Bryophytes, the evidence of geological records often proves altogether inadequate and conveys no very exact idea of the real phylogeny. As living plants constantly approximate to the ancestral type as we descend in the scale, so likewise a similar approximation must be exhibited in earlier geological time, and this slight differentiation of primitive forms, which are very imperfectly known to us through mere fragments of the original plants, is one of the most prolific sources of error in paleobotany, and has resulted in the constant shifting of plants from one position to another.

On theoretical grounds the Thallophytes must have flourished in the very earliest periods of the earth's history, and their remains should occur in rocks of the Laurentian age, but if we leave out of consideration those very problematical forms which have sometimes been held to represent plants from the early paleozoic, nothing recognizable appears until the Silurian, in

the later portions of which we are abruptly confronted with algæ of gigantic dimensions and a high degree of organization, thereby implying the existence of a long line of ancestors in the earlier geological periods, of which all traces seem to have disappeared. Passing into the Devonian, such types gain greater prominence in point of numbers, and thence on to the present the successive formations give evidence of the continuous development of this type of plant life; and while in Nematophycus, Chondrites, Lagynophora and Bacillus we find well-developed representatives of types known at the present time, their ancestral forms are to be sought in the Laurentian and portions of the early Paleozoic, where the only evidence of their former existence is to be found in the abundance of graphite and other forms of carbon. The most perishable of all plants, the Thallophytes, readily yield to that decay which is the invariable antecedent of petrifaction, and the slight residue of structure which might remain is commonly obliterated in the further metamorphosis of the rocks in which they are held. It is therefore altogether exceptional that such plants should be preserved in recognizable form, and their value for phylogenetic purposes, although very limited, acquires an unusual interest and importance. This is eminently true of the very plants through which the line of direct descent passes, since the green algæ are, of all the group, among the most perishable. For these reasons it is in no way surprising that additional representatives of the Thallophytes among fossil plants are rare, that such plants as are found add but little to our knowledge of descent, and that they fail completely to illumine the line directly ancestral to the Bryophytes—the evidence so far accumulated bearing altogether upon side lines represented by relatively durable remains.

Among the higher Thallophytes, a few additions have been made to the Charophyceae by the recognition of the characteristic fruits in the Lower Tertiary of Wales, Ohio, where two species—*C. Stantoni* and *C. compressa* of Knowlton are found. Fruit-like bodies having the external characteristics of *Chara* have also been observed in the Devonian at the falls of the Ohio, thus giving to this group of plants the possibility of a very ancient lineage which is justified on theoretical grounds. The very fragmentary remains so far known, the preservation of which depends upon their calcareous investment, nevertheless serve to throw no additional light upon previous knowledge. Migula has suggested that these plants occupy a position superior to the Thallophytes as a whole and coordinate with the other great divisions of the plant world. This view has been adopted by Seward in his most recent contribution to paleobotany, and Campbell also regards it as deserving recognition. To the solution of this question, however, the fossil representatives contribute no information not derivable from existing species.

Among the Phaeophyceae considerable interest has attached for a number of years, to a remarkable fossil originally described by Dawson as Prototaxites under the impression that it represented a primitive Gymnosperm allied to the Taxaceae. This view was disputed by Carruthers, who was the first to determine the algoid nature of the organism, and he assigned to it the name *Nematophycus*. Subsequent investigations of North American material amply justified this view, and Dawson was led to so far modify his original opinion as to employ the name *Nematophyton*. Several provisional species from the Silurian and Devonian of America have been recorded, and to these there have been added three species from the same formations in Europe. Carruthers has been led to suggest a possible

relationship to the modern Siphoneae, but an extended study of American forms leads to hesitation in giving this opinion unqualified acceptance. Several years since, the belief was expressed that there were grounds for supposing a relationship with Laminarieae, and the genus *Lessonia* was cited as likely to afford the best means of comparison, but the impossibility of securing suitable material caused such studies to be deferred. Recent studies by MacMillan have given us a detailed account of the morphology of this extremely interesting but not readily accessible plant, and from material which he has kindly supplied the writer, it is to be noted that very striking points of resemblance to *Nematophycus* appear. Without entering into details on the present occasion, it may suffice to indicate that similar growth layers, the presence of a distinct cortical structure, the general disposition of the elements as seen in transverse section, and the presence of radial spaces, occupied by elements of the medulla which there assume a horizontal position and develop special relations to one another, are all features which point with considerable force to possible relationship. Beyond these facts, however, our present knowledge respecting the phylogeny of this group of plants will not permit us to go.

The Bryophytes constitute another group which, from their delicate organization, are not likely to be found either in very considerable numbers or in a very perfect state of preservation as fossils. They nevertheless occupy a most important position in plant evolution, since they are considered to constitute the connecting link between the green algæ and the higher vascular plants, their derivation from the former being through the thalloid liverworts, while their algoid ancestry also appears in the filamentous protonema of the true mosses and in the motile spermatozoids of the entire group. From the phylogenetic position of these plants as determined by a study of existing forms, we are led to infer that they must have had their origin in very early geological times—antedating the more fully organized terrestrial forms of which they are to be considered the ancestors. There is thus good reason for supposing them to have flourished as early as Devonian or even Silurian time, but the evidence derivable from the rocks shows no recognizable remains of these plants until we reach the later Mesozoic, while it is not until Tertiary time that they become clearly defined. It is, therefore, reasonably certain that the solution of questions relating to the origin of this group must rest altogether upon evidence derived from a study of existing species—to such, fossil botany has as yet contributed nothing.

From their more durable structure, which offers a higher degree of resistance to the operation of decay, the vascular plants have always been found in the best state (sometimes remarkably perfect) of preservation, and they have therefore always presented the best of opportunities for phylogenetic studies, more especially in consequence of the great abundance of their remains and the increased probability of deriving data of permanent value from them. In considering the distribution of these plants in geological time, one is impressed not so much with their often extensive vertical range, as with the abruptness with which special types appear through representatives of a high degree of organization. This has already been noted in the case of the Thallophytes, and among the vascular plants it is no less remarkable. The ferns which first appear in the Devonian are represented not only by foliage and fruit, but also by stems of large dimensions; the *Cycads* abruptly appear in the Jurassic and Cretaceous while the Angiosperms as suddenly appear in the Mesozoic, where they gain great prominence in the Cretaceous formation.

From these and other similar examples we are justified in the inference that such highly organized types represent the culmination of lines of ancestors which must have extended far back into the earlier geological periods, a view which gains weight from recent researches.

Among the ferns the Eusporangiateae are recognized as representing the primitive forms, and they constitute the starting point for two parallel lines of descent, one of which leads to the Leptosporangiateae and finally culminates in the Heterosporeae. Recent studies of *Parka decipiens* have shown that this hitherto problematical organism from the Devonian is unquestionably to be regarded as one of the heterosporous felicineæ, possibly allied to Marsilia. The occurrence of this plant in the same horizon as that in which the Eusporangiateae first appear, somewhat abundantly and in a high state of development, is of great significance, since it points without question to the origin of the ferns at a very much earlier date, probably not later than Silurian time.

In studying a new Taeniopterid fern from the Lower Coal Measures of the Carboniferous of Henry county, Missouri, Mr. D. White notes certain resemblances on the one hand to *Alethopteris*, and on the other to *Taeniopteris*, to which he assigns his plant under the name of *T. missouriensis*. Discussing this plant in relation to other known forms of the Marattiaceae, he endeavors to construct a hypothetical relationship which shows a *Megalopteris* stock of the Lower Devonian, to give rise in the Middle Devonian to *Neuropteris*, *Alethopteris* and *Megalopteris* proper. Thence through successive formations these three lines of descent lead to *Dictyopteris* and *Odontopteris*, which culminate in the Permo-Carboniferous, and to *Danaeopteris*, *Lomatopteris*, *Oleandridium*, *Taeniopteris*, etc., which either culminate or have their origin in the Trias, while *Angiopteris* originates at this latter horizon and *Danaea* makes its first appearance in the Jurassic. The hypothesis is a suggestive one, but as the fructification of these plants is wholly unknown, and as we have no data derived from the internal structure, while the relations exhibited are based entirely upon leaf characters, it is impossible to attach very great weight to it except as a possible starting point for further observations.

Recent studies of modern Equisetaceae and the various species of Calamites by Jeffrey, offer some very suggestive conclusions respecting the phylogeny of this most interesting group of plants now in the later stages of decline. Embryological studies show that similar structures in the prothalli, the absence of a basal cell from the archegonia and the epibasal origin of both root and shoot, serve to establish a definite connection between the Equisetaceae and the Homosporous Lycopods, a relation which is further justified by a comparison of the stem structure. He also shows that the close agreement between the Equisetaceae and the Sphenophyllaceae makes the latter the protostelic ancestors of the former. An acceptance of these conclusions would carry our knowledge of the phylum back to Lower Devonian time, and show that while the direct line of descent passes through the Sphenophyllaceae and Equisetaceae, the Calamites arose as a side line.

The phylogeny of the Gymnosperms has for many years constituted a subject of the foremost importance and interest, and it has received the most careful consideration at the hands of both paleontologists and botanists. The deep interest which centered so largely in the Cycadaceae, has within the last few years received additional strength not only through the discovery of those remarkable collections of *Cycads* from the Mesozoic, which Ward

has already described on the basis of their external characters, and which Wieland is now engaged in studying from the standpoint of their internal structure; but also from the very noteworthy observations of Weber and Hirase respecting the occurrence of motile spermatozoids in Zamia and Ginkgo. Our knowledge of the North American *Cycads* adds nothing as yet to the phylogeny of these plants as determined by European investigators, but the progress of the studies of the Yale material will be watched with the greatest interest, in the hope that they may yield facts of importance in this connection. In the meantime, however, the deep significance of conclusions derived from the study of European material justifies a brief reference to the position of our present knowledge of this group of plants, which may be said to have commenced with a recognition of the similar characteristics possessed by a small group represented by Noeggerathia, Medullosa, etc., characters which pointed both to a filicinean and cycadean connection, but which were too poorly defined to permit the assignment of the representatives to any specific position. A recognition of the identity of Medullosa and Myeloxylon as suggested by Solms-Laubach and later confirmed by Schenck and Weber, served to prepare the way for a clearer conception of the relations existing between the individual members as also with other groups, and this gained final expression in Potonié's determination that Noeggerathia, Medullosa, Lyginodendron, Heterangium, Cladoxylon and Protopitys represent a distinct group of plants having an affinity with the ferns on the one hand, and with the cycads on the other, thereby becoming of ordinal value. He therefore established the name Cycadofilices as a proper recognition of the important position occupied by them. An additional contribution to our knowledge of this exceptionally interesting group of plants has been given by D. H. Scott in a study of Medullosa anglica, which he shows to have a probable filicinean connection through the Heterangium type. He further concludes that while the Medulloseae are to be considered as having affinities with the Cycadaceae in a broad sense, they really constitute a short, divergent branch of the phylogenetic tree.

The ancestry of the Coniferæ has excited an interest almost as profound as that centering in the *Cycads*, and although we are enabled to trace these plants more or less fully back to Silurian time, we are as yet unable to establish their relation to an inferior group, as in the case of the *Cycads*. Our present knowledge of the descent of the Coniferæ rests chiefly upon a recognition of that line of ancestry which passes through Cordaites and culminates in the Araucarian type. This has been gained by a careful study of the structure of the wood, as also of the foliage, inflorescence and fruit, as obtained from numerous European localities, notably those in France. Extensive collections of North American Cordaitæ are represented by the wood and foliage only, and though their value for phylogenetic purposes is thereby relatively limited, they have nevertheless contributed important data derived from a study of the stem structure, and afford a striking illustration of the superior importance of those histological methods first employed in such connection by Witham, the value of which was so strongly insisted upon by Brongniart. Apart from the general evidence derived from this material, which points with great force to the development of the Araucarian type, the structure of the stem is frequently preserved with such perfection as to permit recognition of important phases in the evolution of structural features. As long ago as 1840, Don pointed out that in the tracheids of *Cycas revoluta*, scalariform structure may occur at one end and bordered pits at

the other. In 1869 Williamson was able to point to similar structural modifications in *Dadoxylon*, and to show that regularly transitional forms gave proof of the derivation of the bordered pits from scalariform structure. Recent studies of North American Cordaitæ have given conspicuous examples of the same kind, and show that a continuous series of radial sections will display regularly transitional forms—often combined in the same tracheid—passing from the spiral vessels of the protoxylem through scalariform vessels, thence into tracheids with transversely elongated bordered pits, which successively become shortened up until there is developed the typical, multiseriate, hexagonal and compactly crowded bordered pit so well defined not only in the Cordaitæ, but also in the modern Araucarieæ. These facts possess the deepest significance from a phylogenetic point of view, since they afford an additional and reliable indication of derivation, and in the present connection, they serve to point with considerable force to the idea that among modern Conifera, the widely-separated bordered pit which in many instances wholly disappears is for that line of descent the culminating form of this type of structure; while in the Angiosperms the modification has been carried to a greater extreme and involves the reduction of the pit to the form of a simple slit or pore, and ultimately to its complete obliteration as a final expression of the secondary growth of the cell wall. Structural alterations of this nature involve also a more or less profound influence upon functional activity as expressed in the distribution of nutrient material.

I have thus endeavored, within the limits of the time at my disposal, to briefly indicate some of the more prominent directions in which paleobotanical activities have developed in North America within the last decade. While this review shows that some substantial progress has been made, that much has been accomplished in the direction of laying the foundation for future studies, and that the study of fossil plants is gaining greater prominence as a necessary aid to our knowledge of plant descent, it also brings into relief the fact that progress in this latter direction must of necessity be slow, and the result of laborious methods of investigation extending over such long periods of time as will permit the accumulation of great stores of material, and the careful piecing together of fragments which separately have little or no significance. Nevertheless the rapid progress which has marked our knowledge of fossil plants during the last twenty years, and the acceleration of this progress within the last two decades, together with a greater appreciation of the fundamental importance of such studies in questions of relationship, afford much ground for regarding the future of paleobotany on this side of the Atlantic as one of promise.

DETERMINATION OF THE SUN'S DISTANCE FROM OBSERVATIONS OF EROS.

The tendency of the time toward thorough organization and cooperation in large enterprises is well illustrated in modern astronomy. Twenty-five years ago, a dozen leading observatories, by mutual agreement, divided the northern sky into zones in such a way that their meridian circle observations would combine to form the excellent Astronomische Gesellschaft star catalogues; and this great work is now nearing completion. The work of charting the sky by means of photography was similarly organized by the Astrographic Conference in Paris some ten years ago.

About fifty of the principal observatories of the world are now cooperating in a great program of observation for improving our

knowledge of the distance between the earth and sun. Fully half the resources of the Lick Observatory, the Lick Astronomical Department of the University of California, have been devoted to this work for three months past, and the observations will continue another month.

The determination of the value of this astronomical unit of distance is one of the most famous problems in the science, and a great variety of methods has been used. Perhaps the best determination is that made by Sir David Gill, of the Cape of Good Hope, from heliometer observations of the nearer asteroids. The four hundred small planets —asteroids—discovered up to 1898 all move in orbits situated entirely outside the orbit of Mars. The observations of Victoria, Iris and Sappho, which approach nearer to the earth than any of the other members of the asteroid group, led to the conclusion that the average distance from the earth to the sun is about 92,900,000 miles. The unavoidable errors to which all such observations are subject leave an uncertainty of some 150,000 miles in this value: it may be too large or too small by this amount.

The accuracy of results obtained in this manner depends upon the distance of the observed body from the earth and upon its definiteness as a point of observation. Mars possesses the advantage of being nearer the earth than the asteroids, but this advantage is greatly outweighed by the fact that an asteroid-point can be observed much more accurately than a large planet-disk. Gill's splendid work left much to be desired, but there was no prospect that his value of the unit could be improved with instruments now available.

An asteroid discovered by Dr. Witt in Berlin in 1898, to which he gave the name Eros, is very remarkable in that its orbit lies partly within and partly without the orbit of Mars. It approaches the earth more closely than any other member of our system, except the moon. The forms and relative positions of the orbits of the earth, Eros and Mars are shown approximately by the accompanying diagram, Fig. 1. The

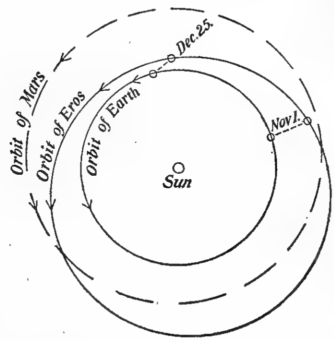

FIG. 1.

orbits of Mars and Eros appear to intersect, but this is merely apparent, from the projections of the two on the plane of the paper. The plane of the orbit of Eros makes an angle of about eleven degrees with the plane of the orbit of Mars (and the earth), and the two orbits are situated like two adjacent links of a chain, without approaching each other very closely.

As soon as the orbit of this wonderfully located asteroid was computed and published, astronomers realized its possibilities for improving our knowledge of the sun's distance. As stated above, an asteroid's value for this purpose depends upon its closeness to the earth. The distance of Eros at this opposition will have a minimum value of twenty-seven million miles. Unfortunately, the more favorable opposition of 1896, when the distance diminished to fifteen million miles, was not available, as the planet remained undiscovered; and an equally good opposition will not occur again for a quarter of a century.

In outline, this method of measuring the

sun's distance is exceedingly simple; but in detail, it is exceedingly complex and technical. The nature of the problem may be explained from Fig. 2.

FIG. 2.

If the earth is at E and the asteroid at A, an observer on the earth's surface at P will see the asteroid projected on the sky at P', whereas an observer at L will see it at L'. If the distance PL is known, as it is, and the angle PAL is obtained from the observations, the data for solving the triangle PLA are at hand, and the distance EA may be obtained by simple computation. As a second step in the solution, the orbit of Eros will be determined very accurately, basing the determination upon Newton's law of gravitation. It will then be a simple matter to compute the ratio of the earth's distances from the sun (ES) and the asteroid (EA). The distance EA having already been determined in miles, the desired distance ES will follow.

If two observatories on opposite sides of the earth secure observations simultaneously, say at P (Pukowa in Russia) and at L (Mt. Hamilton), the desired data are theoretically complete; but practically they are insufficient. There are unavoidable errors in the measurement of the very small angle PAL, and in the assumed positions of the two observatories, which will be materially reduced by having observations made at a large number of stations. The direct distance between the Pulkowa and Lick Observatories is about 5,000 miles. This is a base line from which to measure a distance of 27,000,000 miles, and thence the three-and-one-half-fold greater distance to the sun. The form and the dimensions of the earth thus enter directly into the problem. An error of a quarter of a mile in the assumed length of the base line leads to a large error in the final result.

Instead of simultaneous observations made in the morning in Russia and in the evening in America, the angle PAL can be determined by evening and morning measures secured at one station.

The July conference of astronomers at the Paris Exposition afforded an opportunity for a hurried formation of cooperative plans to secure the observations needed. It may be said that every one of the contributing observatories is devoting to this problem all its resources which in any way promise to improve the results. The measures are most advantageously made in November and December; and perhaps a hundred observers are giving their time to this work. The reductions will require one or two years' labor, and the value of the sun's distance, resulting from a combination of all the work of all the observatories, will probably not be available for two or three years.

The Lick Observatory is contributing as follows:

Astronomer R. H. Tucker, assisted by Mr. Crawford, is securing two meridian-circle observations of each of 700 stars, to determine their positions with the utmost accuracy. These positions, furnished by perhaps a dozen or more observers, will form the triangulation system, or groundwork, upon which the whole structure of the determination will be based.

Astronomer W. J. Hussey and assistant-astronomer R. G. Aitken, with the assistance of Mr. Wright and Dr. Reese, are using the great 36-inch telescope five or six nights per week, weather permitting, to measure the evening and morning positions of Eros with reference to the fixed stars in the asteroid's vicinity. The positions of these reference stars will be secured by means of photographs of the regions

taken with eight or ten telescopes, mostly in Europe.

Assistant-astronomer C. D. Perrine, assisted by Mr. Palmer, is employing the Crossley Reflector every clear night to obtain photographs of Eros and its surrounding stars, to furnish the planet's accurate position in the evening, in the morning, and on the meridian. The measurement of these plates will be a heavy task. Fortunately, Professor Rees, Director of the Columbia University Observatory, has volunteered to measure them. Columbia University is the only institution in this country which has had experience in measuring such plates, though many foreign observatories have long been doing similar work.

The planet Eros is now of about the 9.3 magnitude. It is easily visible in a three-inch telescope.

W. W. CAMPBELL,
Director of the Lick Observatory.

ON THE NATURE OF THE SOLAR CORONA, WITH SOME SUGGESTIONS FOR WORK AT THE NEXT TOTAL ECLIPSE.

IN an article on the corona, published in the November number of the *Astrophysical Journal,* I suggested a method by which the existence of the Fraunhofer lines in the spectrum of the corona might be detected. The method was based on the supposition that the light emitted by the particles in virtue of their incandescence, so overpowers the reflected sunlight that the lines are invisible. That the coronal light is strongly polarized is well known, and there is scarcely any doubt but that the polarized light is reflected sunlight. If now a Nicol prism be placed before the slit of the spectroscope in such a position as to transmit the polarized radiations, these will be allowed to pass with almost undiminished intensity, while the emitted or unpolarized light will be reduced in intensity by one-half. The great change in the ratio resulting might easily be sufficient to bring out the dark lines distinctly. I feel firmly convinced that this experiment should be tried at the Sumatra eclipse of next May, for I have successfully accomplished it in the laboratory with an artificial corona. It was found that a gas flame in a strong beam of sunlight shone with a pure bluish-white light, due to the reflection or rather scattering of the sunlight by the minute carbon particles.* The flame thus illuminated showed the Fraunhofer lines distinctly, but by reducing the intensity of the sunlight a point was reached at which they disappeared, and the spectrum appeared continuous. The light scattered by the flame was found to be *completely* plane-polarized in certain directions, giving us just the required conditions, namely particles emitting a continuous spectrum, and scattering a polarized solar spectrum. In front of the slit of the spectroscope a Nicol was arranged in such a manner that it could be drawn into and out of position by a cord. The Fraunhofer lines could be made to appear by sliding the Nicol in front of the slit, and disappear by drawing it away. While it does not by any means follow that the use of a Nicol on the actual corona will bring out the lines, the experiment seems to be well worth trying, as it would furnish further information regarding the relative intensity of the emitted and reflected light. Another interesting point is that the minute particles in the flame do not scatter the longer waves, the flame reflecting practically no red or orange light. Thus the Fraunhofer lines can only be traced up to about the D lines. By gradually reducing the intensity of the sunlight they disappear first in the yellow, then in the green, blue, and violet in succession.

* A photograph of the flame with a spot illuminated by powerful convergent beams of sunlight furnishes a beautiful proof of the existence of solid particles in the flame.

This indicates that our chances of detecting the lines in the spectrum of the corona will be greatest in the photographic part of the spectrum. Moreover, it appears to explain the absence of radiant heat in the light emitted from the corona, the particles being too small to scatter these longer waves to any appreciable extent. Abbott, of the Smithsonian party at Wadesboro, found the corona cold in comparison with his bolometer, and infers from this that the corona neither reflects sunlight nor emits light in virtue of incandescence, expressing the opinion that the luminosity is analogous to that of vacuum tubes transmitting electric discharges. It seems to me that the polarization of the coronal light makes this theory untenable, and that the absence of heat rays can be explained fully by the small size of the particles. I am aware that the absence of radiant heat in the *emitted* light has yet to be accounted for. My own notion, based on experiments which are now in progress, is that the reflected or scattered light is vastly in excess of the emitted, and that the absence of the Fraunhofer lines is more probably due to line-of-sight motion of the particles, than to simple drowning out by emitted light.

My experiments on the ratio of emitted to reflected light of a body brought to incandescence by powerful solar radiation are not yet completed, consequently I do not yet feel prepared to make any very positive statement in regard to this matter. A full account of this work will appear shortly in the *Astrophysical Journal.*

Any observers planning to use a Nicol prism in connection with a spectroscope in the manner described will find a gas or candle flame illuminated with a beam of sunlight concentrated by means of a large mirror or lens, extremely useful in making preliminary experiments.

For work on the polarization of the corona I believe that the artificial corona described elsewhere will be found most useful for preparatory work. Not only is it polarized, and polarized in the same way as the real corona, but it resembles it in a most striking manner, and can be easily made of the same brilliancy. It would be well to work with particles of different size, giving different percentages of polarization, and the picturesque refinements for producing the polar streamers could of course be omitted. For work of this sort it would be well to use a lamp with a ground glass bulb, as the conditions of illumination would then more nearly approach those in the real corona.

Data regarding the plane of polarization in the streamers would be useful in formulating a theory of the streamers. These, it seems to me, can be conceived as formed in two ways: they may be streams of coronal particles moving in curved paths, in which case the plane of polarization should be everywhere strictly radial, or what is extremely improbable, they may be caused by divergent beams of light coming from the polar regions of the sun and moving in curved paths, owing to the rapid decrease in the refractive index of the sun's atmosphere in an outward direction. If this were the case, the plane of polarization would turn with the streamer.

This latter hypothesis is extremely visionary, and I do not present it seriously, for it is almost impossible to conceive of any way in which the isolated beams of light could be formed, unless perhaps by vortex funnels more highly luminous than the surrounding surface of the sun. Such fanciful speculations are hardly worth indulging in, though they have interested me for the moment in connection with the matter of the possible curvature of light rays in the sun's atmosphere alluded to in a recent paper by Julius in the *Astrophysical Journal.*

University of Wisconsin.

CHICAGO SECTION OF THE AMERICAN MATHEMATICAL SOCIETY.

THE eighth regular meeting of this Section was held at the University of Chicago on Thursday and Friday, December 27 and 28, 1900. The Section was organized in April, 1897, under a by-law of the Society which provides for conducting in any locality periodic meetings for the reading and discussion of mathematical papers, and since then has met twice a year, in April and December. During this period a total of 128 papers, by fifty-two different persons, have been read before the Section.

The election of officers, which occurs regularly at the Christmas meeting, resulted in the re-appointment of the Secretary, Professor Thomas F. Holgate, and the choice of Professor E. J. Townsend and Professor James B. Shaw for members of the Program Committee.

The following papers were read:

1. PROFESSOR E. H. MOORE: 'On the uniformity of continuity.'

2. PROFESSOR ARTHUR S. HATHAWAY: 'Quaternions and four-fold space.'

3. PROFESSOR IRVING STRINGHAM: 'On the geometry of planes in a parabolic space of four dimensions.'

4. DR. F. H. SAFFORD: 'Flow of heat in two dimensions.'

5. MR. A. C. LUNN: 'Certain mathematical aspects of experimental science.'

6. MR. E. A. HOOK: 'Some properties of circulating decimals.'

7. PROFESSOR ARNOLD EMCH: 'Note on the congruences of twisted curves.'

8. PROFESSOR H. B. NEWSON: 'A generalization of the Wessel-Gauss-Argand diagram.'

9. DR. F. R. MOULTON: 'On straight line solutions of the problem of n bodies.'

10. DR. GILBERT A. BLISS: 'Geodesic lines on an anchor ring.'

11. MR. FRANZ A. LA MOTTE: 'On the determination of the algebraic equations invariant under Tschirnhausen transformations, with the parameter representation of all such irreducible equations, with rational coefficients, of the third and fourth degrees.'

12. PROFESSOR E. J. TOWNSEND: 'Functions of two real variables which are continuous with respect to each variable.'

13. PROFESSOR L. E. DICKSON: 'The group of the equation for the twenty-seven lines on a general cubic surface.'

14. PROFESSOR OSKAR BOLZA: 'Concerning the expression of Abelian integrals in terms of a fundamental set of integral functions.'

15. DR. J. C. FIELDS: 'Proof of the Riemann-Roch theorem and of the independence of the conditions for adjointness.'

16. PROFESSOR OSCAR SCHMIEDEL: 'Two reduction formulas applicable to certain particular integrals.'

17. PROFESSOR E. B. SKINNER: Some forms which remain invariant with respect to certain ternary monomial substitution groups.'

18. PROFESSOR JAMES B. SHAW: Note indicating a new development of a determinant.'

19. PROFESSOR E. H. MOORE: 'On double limits.'

20. PROFESSOR E. H. MOORE: 'Concerning the fundamental propositions of the theory of proper definite integrals.'

21. MISS IDA M. SCHOTTENFELS: 'Proof of the existence of a particular substitution group of degree 21 and order 20160.'

In addition to the above Professor Hathaway presented a paper introducing a general discussion on the subject 'Pure Mathematics for Engineering Students.'

THOMAS F. HOLGATE,
Secretary of the Section.

EVANSTON, ILLINOIS.

WISCONSIN ACADEMY OF SCIENCES, ARTS, AND LETTERS.

THE thirty-first annual meeting of the Academy took place at Milwaukee, December 27 and 28, 1900. The following papers were read and discussed:

'An example of a theoretical system of weight-factors, of ready application in the solution of observation equations,' by Albert S. Flint.

'Harmonic curves of three frequencies.' (Second paper.) With exhibition of stereograms drawn by E. A. Hook, by Charles S. Slichter.

'On repeating decimals,' by E. A. Hook.

'On an improved method of determining latent heat of vaporization,' by Louis Kahlenberg.

'A campaign cry of 1844,' by H. J. Desmond.

'Early political platforms in Wisconsin,' by John G. Gregory.

'Personal names, their etymology,' by James D. Butler.

'Shakespeare's knowledge of criminal psychology,' by Frank C. Sharp.

'Determinism, decrees and immutable law,' by Charles C. Caverno.

'Some recent observations on the migration of birds,' by H. A. Winkenwerder.

'The plankton of Green Lake and Lake Winnebago,' by C. Dwight Marsh.

'The cause of cleavage in rocks,' by C. K. Leith.

'The supposed lessening of geyser activity in the Yellowstone National Park,' by D. P. Nicholson.

'The orientation of stream channels as related to geological structure,' by William H. Hobbs.

'The old tungsten mine at Trumbull, Ct.,' by William H. Hobbs.

'The future of the clay and cement industry in Wisconsin,' by Ernest R. Buckley, Associate Director of the State Geological Survey.

The following papers were read by title:

'On the thermal conductivity of common woods,' by L. W. Austin and C. W. Eastman.

'The expansion of wood due to the absorption of water,' by L. W. Austin, G. S. Cassels and W. H. Barber.

FRANK CHAPMAN SHARP,
Secretary.

SCIENTIFIC BOOKS.

Foundations of Knowledge. By ALEXANDER THOMAS ORMOND, McCosh Professor of Philosophy in Princeton University. New York, The Macmillan Co. 1900. 8vo. Pp. xxvii + 528. Price, $3.00.

Without mincing words, it may be affirmed at once that Ormond's work is a very considerable performance. Not only this. Symptomatic books on philosophy have been none too many these last twenty-five years, and the volume before us betrays many symptoms of interest in relation to matters fundamental. Accordingly, even if it be 'meant as a first rather than a final word on the topics with which it deals' (Preface, xxv), it cannot escape the sharp analysis that all primary achievements deserve and, indeed, demand. Further, the 'General Introduction' betrays so excellent a sense of the recent historical situation, especially in British-American thought, that the things Ormond has left unsaid throw no little light on those to which he has committed himself. As the book is a first word, and largely epistemological at that, in view of favors to come, I should like to express the hope that, in Ormond's creed, things are lawful in epistemology which must be suppressed sternly in metaphysic.

The main body of the exposition has been divided into *three* 'Parts.' In the *first*, Ormond deals with 'Ground-Concepts of Knowledge.' What he attempts here might be called a clearing of the air. That is to say, centuries of discussion and of common usage have caused many hoary associations to cluster round certain terms. Every one is aware what the words, 'Experience, Knowledge, Reality,' mean; yet, equally, no one is aware. Otherwise, these counters cover so much that few stop to deploy their implications, and the interpretation alters with the ear that hears. Personal tendencies, customary environment of intellectual habit and the like, vary from man to man, from community to community. The 'experience meeting' of the pietist, the 'experience' demanded by electors to a vacant office, 'experience' with Mr. Spencer, and 'experience' as the latter-day idealist thinks of it, are by no means the same affair. Accordingly, with true instinct, Ormond proceeds, first, to state his view of the general implications of 'Experience, Knowledge, Reality,' and a very sensible, non-partisan view it is. "We may define experience as the sum of these personal activities by means of which a conscious self reacts upon its object or not-self, and translates it into realized content, these activities being inclusive of thought, feeling and will; or, objectively—the system in which these activities are included" (50). "The notion of reality includes a synthesis of being and manifestation" (64). "The method of knowledge, as we have conceived it, is an embodiment of the inner dialectical process by which the content of experience is reduced to the content of knowledge" (104). Such are the essential statements.

The *second* Part reviews the 'gradual development of the knowing processes,' and is entitled, 'Evolution of the Categories of Knowledge.' At this point, even if one have not noted its presence previously, the modern outlook of the work becomes abundantly apparent. To be specific, the contemporary de-

mand for a dynamic, as opposed to a static, view of experience receives satisfaction. After analyzing the nature of the categories, Ormond proceeds to thresh the old straw of Space, Time, Quantity, Quality, Cause and Substance, offering, however, certain stimulating novelties, particularly in his treatment of the two last; this, even if we demur to his allegations that 'The notion of agency is a persistent element of that of cause' (174), and that 'the category of substance represents the mode by which experience realizes those points of rest or permanence in its world which are necessary in order to render the series of changes possible' (192). Thence he passes to the subject so much agitated and so vitally interesting to-day—to 'Community or Interaction, the Dynamic Consciousness, the Æsthetic Categories, the Subject Consciousness, Categories of the Subject Consciousness, the World of Individuals, the Consciousness of Community.' The point at which he elects to take up the 'Subject Consciousness' is worthy of especial remark. Every praise ought to be accorded this abundant recognition of the newer insights and problems. Similarly, one cannot fail to be struck favorably with the frank manner in which Ormond tackles this task, even although he proceeds from presuppositions that antedate the dynamic categories, do not grow out of them, nay, as the strong probability runs, are forbidden, if not exploded entirely, by them.

To readers of SCIENCE, the *third* Part presents much matter of genuine interest. Greatly daring, Ormond has christened it 'The Transcendent Factor in Knowledge.' But names need not frighten us, when we discover that he places within these dread limits that vital modern problem, the relation between science and philosophy. Moreover, in outlining this relation, he formulates what must be taken as his characteristic contribution to pending metaphysical inquiries—the concept of *transcendency within experience.* "We have seen that science deals with the transcendent and that metaphysics has something to do with experience. * * * The discussion * * * has put us in a position to see that one of the points of difference consists in the fact that the aim of science, in so far as it finds it necessary to recognize the transcendent at all, is simply to employ the concept of it in determining the nature of the relative in experience. This accounts for the fact that science stops in its attempt to define the transcendent at that point where that process ceases to be necessary to the definition of the relative. Metaphysics, on the other hand, is directly concerned with the determination of the transcendent, not so much as a principle for the definition of the relative in experience, as for the complete determination and satisfaction of the relative experience as a whole through the grounding of it in that which is absolute and complete. Having for its aim then the grounding and completing of the relative experience itself in that which transcends it, the determination of this transcendent nature becomes a matter of direct interest to it, and its attitude toward the transcendent is from the outset, therefore, different from that of science" (323–4).

At this point precisely, one must take issue with the author. If what he says about the mission of metaphysics be true, then science may once more say to philosophy what she has sometimes said before: 'All right, I'll keep the inside of the house, you may do as you will with the outside.' For, by definition, the transcendent happens to be the super-experiential, that concerning which anything may be said; and we cannot too often recall that anything and nothing are identical. To attempt to fill out this word with meaning, as Ormond seems to do again and again, is, of course, to negate transcendency. The fact is that Ormond (this is part of his great interest) represents a point of view which, unconsciously, mediates between the old pre-Kantian dualism and the desiderated organic monism—a theory still in the air, but, nevertheless, the sole defensible ground of scientific dualism, and also of the conservation of those aspects of experience which Ormond has in mind when he writes 'transcendent.' Had he ploughed longer with the heifer of science, he might have earned vouchers admitting him to this philosophical paradise; as it is, he who runs may read the flaw in the credentials presented here.

Consider the following passages, for example. "The real, then, is possible content of con-

sciousness and will be found to be a transcendent term in relation to an actual consciousness. It will include the realized content of the actual consciousness; also that which is simply present *in* or *to* consciousness, together with an extra-conscious sphere which exists as yet only as implicate or postulate" (90). The *extra*-conscious as implicate of consciousness! Are we able to attach any clear idea to what is either unthinkable or else a concatenation of mere words? Again, in Ormond's definition of Category, the cloven-hoof of the Devil whose delight lies in shattering human experience, plants itself firmly. "A category may then be defined; subjectively, as the constitutional mode through and in which the subject-consciousness penetrates its world, and reduces it to ideal content, and objectively, as the form which the world or not-self is obliged to assume in order to present itself to and in consciousness and become content of its world-idea" (117). 'Obliged' were truly a symptomatic term. The problem of the unity of experience seems to be trebled here. For we have a hint of no less than three universes, to wit, a subject-universe, an object-universe and a category-universe. The conception that ideas are forms (the conception, be it remembered, which has retarded so seriously metaphysical advance, and progress in unitary understanding of the world, by rendering science and philosophy alien from each other) has once more elbowed out the hopeful contemporary insight, that ideas are forces; that 'matter,' in so far as amenable to scientific treatment, is intelligent, because intelligible; that the universe is a universe, because built in one piece, and all inclusive. Yet again, (1) "Without cause no beginning of change would be conceivable, but without substance the very notion of change would be absurd. Cause is the principle in accordance with which changes are organized into a mutually dependent system; substance is the principle which in its notion of permanence supplies the condition which our world demands in order that the system of changes may be possible." * * * (2) "The points of rest are relative, therefore, and have their common presupposition in the central activity of self-consciousness" (192–3). Here a very old friend puts in appearance, no doubt with face washed or smeared somewhat, yet with character unaltered. So far as the statement of *process* goes, (1) and (2) land at last in mutual exclusions, as they have ever done.

As Ormond is aware, no modern thinker would deny the existence or the potency of the element which he calls 'transcendent.' But the moment you term it 'transcendent,' you turn it into a kind of waste-paper basket, the convenient receptacle for every sort of inconvenient question. For instance, gravitation is an undeniable fact for the physicist's experience. But whenever you suggest its 'transcendency,' as Ormond's reasoning would, you leave the realm of experience and serve yourself some fine, mysterious feeding. The truth is that gravitation, like other 'ultimates,' is transcendental, and in the sole legitimate sense of this term; that is to say, it is constitutive. Here we come to ourselves again, and well within the sweep of experience. This solid footing reached, we cannot forbear to make the somewhat cruel point that the 'transcendent' is all too apt to provide tranquilizing refuge for those who have learned nothing and forgotten nothing. With these mummies of intellect Ormond has no commerce. But he has wandered perilously near their catacombs; nearer than he knows, possibly, when he writes thus: "There is no reason to suppose then that the distinction between the absolute and relative is other than ineradicable, but, on the contrary, the whole trend of experience tends to confirm what is also a necessity of thinking; namely, that the grounding of any distinction in the absolute is the highest guarantee we can have of its reality and permanence" (419–420). Moreover, the results of this excursion into a field so perilous crop out continually in the curious attitudes he adopts so often in the third Part. What is the man, who is looking for guidance from the very last word uttered in metaphysics, to make of this? "The notion of revelation will be completed then in the idea of the direct function of the transcendent other in introducing a new and superordinary content into our consciousness, the subjective condition of the reception and realization of which is that state of

the subjective consciousness to which the term inspiration is applicable" (491). As a piece of acrobatic audacity, excellent! Yet we may well doubt whether a thinker standing with one foot firmly planted on the Rock of Ages, the other pointing heavenward, has struck the attitude most conducive to progress. Of course, he is so interesting that we should dearly love to secure his photograph to show to our scientific friends, who would be tickled rather than impressed.

To make an end; this book constitutes one of the freshest and most stimulating contributions to philosophical inquiry that we have had for many a day. It represents an enormous advance on Ormond's earlier work. And if the author could but shake himself free from the hypnotic suggestion now exercised over him by the 'transcendent,' he might very easily, in that further discussion hinted in his Preface and looked for with lively expectation by the present writer, produce a book as superior to this as this is to 'Basal Concepts in Philosophy.' In short, Ormond stands on the very edge of the pathway to really constructive leadership.

It remains to say that the publishers have executed their part admirably. Printed at the famous Glasgow press, the book, despite its 540 pages, is light to hold and easy to read. In another edition the usefulness of the index might be much enhanced.

R. M. WENLEY.
UNIVERSITY OF MICHIGAN.

Chemie der Eiweisskörper. Von DR. OTTO COHNHEIM. Braunschweig, F. Vieweg und Sohn. 1900. Pp. 315.

In recent years no book dealing with the proteids and their derivatives has appeared which is so comprehensive and satisfactory as Cohnheim's 'Chemie der Eiweisskörper.' The references to the literature of the subject are unusually exhaustive and include practically every important contribution made prior to 1900. The work of American physiological chemists is cited mostly from abstracts, and some of the more recent papers have not yet found their way into the book; it is to be hoped, however, that the time is approaching when American papers will be studied at first hand in all European laboratories. Cohnheim's 'Eiweisskörper' is something more than a mere compilation of the results of the chemical investigation of the proteids. The author's critical study of the voluminous literature on the subject is indicated by the discriminating judgment with which he has treated many controversial topics and by the succinct manner in which many of the unsolved problems are pointed out. The book is essentially a critical review, and the mode of presentation (for example, of heat coagulation and other physical modifications of the proteids) is decidedly more suggestive than that of most recent writers. In the classification of the proteids Cohnheim follows the latest edition of Hammarsten's 'Textbook,' without claiming for this grouping anything more than a temporary usefulness. The author has proposed, as an innovation, to class those proteids usually termed nucleoalbumins, of which casein is the best defined type, with the simple proteids (Eiweisskörper) under the name of phosphoglobulins; the latter would thus be differentiated more clearly from the true nucleoproteids (in the sense of German writers) to which they bear resemblance only in a few superficial characters. The vegetable globulins (Phytoglobuline) are also treated in the old group of nucleoalbumins, although in the light of our present knowledge they compare more closely with the globulins of animal origin, and many of them, at least, are free from phosphorus.

Without giving a detailed survey of Dr. Cohnheim's book, a few of the better features may be referred to. The analogy in chemical behavior between the proteids and the 'pseudobases' of Hantzsch is pointed out, and a very complete account of the decomposition products of proteids is given, especially of the carbohydrate groups lately identified by various investigators. The sulphur content of the proteids is discussed in detail; and the literature regarding the nitro- and halogen compounds—almost entirely the outcome of very recent work—is collected and reviewed for the first time. In his treatment of the albumoses and peptones the author follows the classification introduced by Hofmeister and his pupils, although the

older worker is by no means overlooked. The more thoroughly studied substances, such as egg- and serum-proteids with their crystalline forms, are taken up at length; and the muscle proteids are presented in the light of v. Fürth's work. To the physiological chemist who has occasion to refer frequently to recent investigations on the nucleoproteids and their derivatives, the careful summary of research in this field of work will be found most helpful. Thirty pages are devoted to the chemistry of hæmoglobin, and the chapter on the albuminoids is fairly exhaustive.

The volume is appropriately dedicated to the memory of W. Kühne.

LAFAYETTE B. MENDEL.

YALE UNIVERSITY.

Treatise on Hygiene. By J. LANE NOTTER. Second edition. P. Blackiston's Sons & Co. 1900.

This is the second edition of the well-known book of Notter and Firth, which itself was founded on the still earlier treatise of Dr. A. E. Parkes.

It is a very comprehensive work, containing nearly eleven hundred pages, and treating of a very wide range of topics, such as, for instance, water, air, food, heating, ventilation, clothing, exercise, construction of houses, vital statistics, and military and naval hygiene.

The book as a whole is excellent, the material is well selected, and the views thoroughly modern. Treating such a wide range of subjects as the authors do, they must necessarily give frequently the opinions of others rather than their own, and this causes at times, where opinions differ, a lack of authority. In a few places remains of earlier editions crop out; thus under malarious soils no mention is made of the mosquito, but in another portion which is devoted to malaria the relation of the insect to the disease is fully stated.

In some places important omissions occur: thus in the preservation of milk cold is hardly alluded to, yet it is almost as important as cleanliness. The number of bacteria considered suitable in milk, 400,000 per cc., seems very high. Taking the book as a whole, it is one that can be thoroughly commended to those who have either a general or a special interest in the study of hygiene.

W. H. PARK.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Journal of Comparative Neurology* for December contains the following articles: 'The Giant Ganglion Cells of Catostomus and Coregonus,' by J. B. Johnston, West Virginia University. The author figures and describes successful Golgi preparations of these transient nerve cells and compares them with the sensory cells in the spinal cord of *Amphioxus* and *Petromyzon,* whose fibers reach the periphery without effecting relations with cells of the spinal ganglion. It is suggested that they are belated neural crest cells which failed to migrate into the spinal ganglia. 'Arrangement and Terminations of Nerves in the Œsophagus of Mammalia,' by Lydia M. DeWitt, University of Michigan. Investigations on the cat and rabbit by the *intra vitam* methylene-blue method. The following types of nerve termination are described: typical motor and secretory fibers from sympathetic ganglia of Auerbach's and Meissner's plexuses, motor fibers from the ventral horns of the spinal cord for the striated muscle fibers of the œsophagus, sensory termini in the mucosa from cells of spinal ganglia, and other sensory fibers, apparently wholly confined to the sympathetic nervous system. 'The Vibrissæ of certain Mammals,' by J. Franklin Messenger, University of New Mexico. The innervation of the hair follicles is figured and a peculiar erectile vascular pulvinus is described. 'The Ophthalmic and Eye Muscle Nerves of the Cat Fish (*Ameiurus*),' by I. S. Workman, Denison University. The cat fish is shown to resemble other teleosts in the absence of a *r. ophthalmicus profundus.* The nerve so named by some anatomists is the *r. ophthalmicus superficialis V,* to which are added facialis fibers for terminal buds on the top of the head. The eye muscle nerves show a ganoidean arrangement. 'On the Homologies of the Chorda Tympani in Selachians,' by H. A. Green, Denison University. The selachian types examined exhibit a pre-spiracular nerve, in addition to the *r. palatinus* and the true pre-trematic ramus for the pseudobranch, which runs down between the

mandible and the hyoid arch and whose morphological relations seem to be the same as those of the mammalian chorda. The editors announce the addition of Dr. Lewellys F. Barker, of the University of Chicago and Rush Medical College, to the staff of editorial collaborators.

IN an article entitled 'The Recent Development of Method in Theoretical Physics,' published in the January *Monist*, Professor Ludwig Boltzmann, formerly of Vienna but now of the University of Leipsic, has presented a trenchant criticism of the philosophical tendencies now dominating physical research. Professor Boltzmann is an outspoken votary of the classical or atomistic physical philosophy which culminated in the labors of Faraday and Maxwell; and after rapidly sketching the rise and development of the mechanical philosophy he proceeds to subject to searching scrutiny the views of the energeticians (Ostwald, Helm, etc.) and the phenomenologists (Kirchhoff and Mach). While not underrating the achievements of either of these two recent schools of physical theory, he asserts that the early acquisitions of the atomistic inquirers could never have been reached by energetics or by phenomenology. To the same number of *The Monist*, MM. Vaschide and Piéron, of Paris, France, have contributed an erudite article on 'Prophetic Dreams in Greek and Roman Antiquity,' for which they have collected from the original sources all the data in the ancient writings relating to oneirology. The remaining articles are an 'Introduction to a Psychological Study of Religion,' by Professor James H. Leuba, and 'Jew and Gentile in Early Christianity,' by Dr. Paul Carus.

THE December number of the *American Geologist* contains the following articles: 'Notes on the Geology and Petrography of Monhegan Island, Maine,' by E. C. E. Lord of Washington, D. C. The works are described as granitic, containing feldspar, olivine, pyroxene and hornblende. The rocks are analyzed petrographically and chemically and compared with rocks from other districts. The mass is frequently crossed by acid and basic dykes which are described and analyses given. 'The Mineralogical and Petrographic Study of the Gabbroid Rocks of Minnesota,' by N. H. Winchell, contains Chapters VIII. to X. inclusive and concludes the series. Chapter VIII. contains a discussion of Quartz Gabbro, in which is given the minerals and their occurrence together with their chemical composition. Chapter IX., Silico ferrolyte, contains a discussion of a rock extremely rich in magnetite containing numerous grains of quartz. This name has been proposed by Mr. Winchell to distinguish the rock from the ferrolyte of Wadsworth, which it resembles. Chapter X., 'Résumé and Conclusions,' contains discussions of the comparative petrography, the mineralogical and chemical composition of the various types of rock studied in the preparation of the report. Next is an interesting article on 'Meteorology of the Ordovician,' by F. W. Sardeson, which is followed by the usual editorial comments, a review of recent geological literature and personal and scientific news.

DR. A. DE WATTEVILLE has resigned the editorship of *Brain*. When accepting his resignation the Council adopted the following resolution: "The Council accepts with great regret Dr. de Watteville's resignation of the editorship of *Brain*, and desires to take this opportunity of recording the deep debt of gratitude that the Society owes him for the way in which he has conducted the Journal for the past twenty years. The Council feels that parting with Dr. de Watteville is an event of great moment to the Society, for he has not only brought *Brain* to a high standard of perfection and secured for it a great European reputation, but even the existence of the Journal at the present time is due to his energetic action at a critical juncture in 1880. Moreover, the Council is mindful that the Society itself took origin on Dr. de Watteville's initiative, at a meeting held at his house, on November 14, 1885."

SOCIETIES AND ACADEMIES.

GEOLOGICAL SOCIETY OF WASHINGTON.

AT the eighth annual meeting, held December 19, 1900, the following officers were elected for the ensuing year:

President, J. S. Diller; *Vice-Presidents*, C. W. Hayes and G. P. Merrill; *Treasurer*, M. R. Campbell; *Secretaries*, David White and F. L.

Ransome. *Members-at-large of the Council*, Bailey Willis, A. H. Brooks, W. Lindgren, G. O. Smith, T. W. Stanton.

The address of the retiring president, Mr. Whitman Cross, on 'The Development of Systematic Petrography in the Nineteenth Century' was delivered in connection with this meeting.

At the 108th regular meeting, held January 9, 1901, the following papers were presented:

N. H. Darton: *Comparison of Stratigraphy of the Black Hills with that of the Front Range of the Rocky Mountains.*

After several years of detailed investigation of the stratigraphy of the Black Hills in South Dakota and Wyoming, a preliminary examination has recently been made of the region southwest to and along the front ranges of the Rocky Mountains across Wyoming and Colorado. The Black Hills are due to a local expansion of a branch of the Laramie range, but the connection underlies a country in great part covered by Tertiary deposits. In the vicinity of Hartville, about 125 miles southwest of the Black Hills, there is a local uplift on this line, affording extensive exposures of formations from the crystalline schists part way up the Mesozoic column. The stratigraphy is here very similar to that of the Black Hills, and all the principal formations from Lower Cretaceous sandstones to the Lower Carboniferous limestone can be distinctly recognized. Along the flanks of the Laramie range, and southward into Colorado, the formations present considerable change, but numerous features of close relationship were observed. In the fine sections at Morrison, west of Denver, there was found an extension of the Purple (Minnekahta) limestone of the Black Hills, having precisely similar stratigraphic relations in the Red beds, and containing some of the same Permian fossil, although these are scarce and not well preserved. The limestone was traced south for a considerable distance and found to merge into a sandy bed which was finally lost in the great mass of coarse red deposits in the vicinity of the Garden of the Gods. Its very distinct occurrence at Morrison affords the means for a precise correlation with the Black Hills region. The underlying mass of coarse sandstone lying against the crystalline rocks represent portions or perhaps all the Carboniferous formations of the Black Hills. The Red beds overlying this Minnekahta limestone at Morrison are gypsiferous shales similar to those of the Red Valley encircling the Black Hills. The Morrison formation lying next above, is, as previous observers have pointed out, the equivalent of the Alantosaurus (Beulah) shales and the marine Jurassic which was traced as far south as the Hartville region, is lacking in the Morrison section. The lower Cretaceous sandstone in the Black Hills has not been recognized in Colorado. The Benton formation presents the same three divisions through the Black Hills region as were determined by Gilbert in southern Colorado. In the valley of the Purgatoire in southern Colorado the Red bed series are represented by red sandstones of moderate coarseness, in the upper bed of which was discovered a bone of a Bolodont which is thought to be of Triassic age. The overlying series of gypsum, limestone, and shale yielded no fossils, but probably comprises a representative of the Morrison formation, for its upper part it least has all the characteristic features of the Alantosaurus shale. It is overlain by so-called Dakota sandstone.

Alfred H. Brooks and Arthur J. Collier: *Glacial Phenomena of the Seward Peninsula.*

The Seward Peninsula, stretching out toward the Siberian coast from northwestern Alaska, separates the Arctic Ocean from Bering Sea.

It consists, topographically, of low, rounded hills whose gentle slopes are often broken by well-marked benches. Above this upland, rise three notable mountain masses. The Kiglowaik range, whose highest peaks reach an elevation of 4,500 feet, is a rugged mountain mass lying some 80 miles north of Nome. To the northeast of this range is another mountain mass, which, extending to the northeastward for some 30 miles, sweeps around the headwaters of Fish River, and joins the mountains east of Golofnin Bay. The York Mountains, the third mountain mass, extend inland from Cape York.

In this region there is no evidence of general glaciation. In fact, there is positive proof

against it. The three mountain masses have, however, as shown by studies of the past season, been centers of local glaciation. In the Kiglow-aik range the valleys are glaciated to an elevation of 500 feet above the valley floor, and the moraines marking the limits of this glaciation were deposited close to tide-water. The evidence of ice action consists of cirques, U-shaped valleys, morainic topography, and glacial erratics. Indeed, in some of the higher valleys still exist the shrunken remnants of the former valley glaciers. These small glaciers, in latitude 65, are, as far as known, the most northerly on the continent.

The high benches and terraces show that the western part of the peninsula has been elevated 600 or 800 feet in recent times. This elevation, however, antedates the maximum extension of the valley glaciers above described.

A. C. SPENCER: *The Physiography of the Copper River Basin, Alaska.*

The observations made by Messrs. A. C. Spencer and F. C. Schrader during the summer of 1900, establish the existence of a peneplain in the Chugatch Mountains, between the coast and the interior basin of the Copper and Chitina (Chittyna) rivers, and in the adjacent mountains at the heads of the Chitina, White and Tanana rivers.

The peneplain is now a dissected plateau with an elevation of more than 6,000 feet. Above it rise Mt. Blackburn and Mt. Natzahat to elevations of several thousand feet, the former, at least, being of extrusive origin. The age of this marked physiographic feature is not earlier than late Cretaceous nor later than Miocene. As the Eocene and Miocene are known to have been periods of baseleveling in western North America, it is probable that the peneplain is of Tertiary age. Whether it should be correlated with the Yukon plateau, considered as Miocene, or whether it is an older feature, has not been determined. It is of the same order of maturity as that plateau, and if it can be shown to be of the same age, its present altitude, several thousand feet above the adjacent portion of the great interior plateau of Alaska, shows that there has been faulting along the scarp which the St. Elias Range and its northwestern extension present towards the northeast.

F. L. RANSOME,
DAVID WHITE,
Secretaries.

BIOLOGICAL SOCIETY OF WASHINGTON.

The 332nd meeting was held on Saturday evening, January 12th.

W. H. Dall exhibited a skiagraph of a number of univalve mollusks, taken by a comparatively short exposure to the X-rays, and yet in spite of their calcareous nature showing the structure and form of the interior whorls very distinctly.

Vernon Bailey showed a specimen of a commercial skin of a grebe, saying that the grebes, as well as other water fowl, were being killed in great numbers in the shallow lakes of Oregon and Washington, particularly in the Klamath lakes, and that it was to be hoped that something might be done to protect these birds before it was too late.

William Palmer exhibited a series of specimens of the Cuban branching fern, *Gleichænia dichotoma*, describing its various stages of growth and comparing them with those of other species.

Frank K. Cameron spoke of 'The Formation of Black Alkali by Plants,' stating that it has long been believed that certain plant varieties cultivated on the arid soils of the West can cause an accumulation of sodium carbonate or 'black alkali.' This question has received some attention in the past, notably by Hilgard in California and Goss in New Mexico. An examination of the question in the laboratory of the Division of Soils, U. S. Department of Agriculture, indicates that in some cases there is an enormous accumulation of sodium in the leaves and stems of certain plants, more than sufficient to combine with the inorganic acids present and therefore in organic combination. On decay this material yields considerable amounts of alkali carbonates, which accumulate on account of the peculiar conditions of moisture and drainage which obtain for soils in arid regions.

The study has led incidentally to a discussion of the phenomena involved in the absorption of mineral salts by plants, from the point of view of the chemist; and lines of investigation

of possible value to the physiologist are tentatively suggested.

The detailed description of the study will appear at an early date in the 'Report of the Field Operations of the Division of Soils for 1900.'

T. H. Kearney discussed 'The Effect of Alkali Salts on the Growth of Seedling Plants,' describing a series of experiments conducted with the assistance of Dr. F. K. Cameron of the Division of Soils, Department of Agriculture, in order to ascertain the relative injurious effects upon plants of the salts characteristic of the so-called 'alkali' lands of the Western States. The salts employed were Na_2Co_3, $MgSO_4$, $MgCl_2$, Na_2SO_4, $NaHC.O_3$, NaCl, $CaCl_2$ and $CaS.O_4$, enumerated in the order of their toxicity so far ascertained; the first of these was the most harmful. Solutions were made in each case on the basis of a normal solution, that is, of the equivalent in grams per liter of the reacting weight of each salt. Young seedlings of *Lupinus albus* were selected for these experiments because of their sensitiveness to toxic substances, and because when proper conditions of germination are maintained their clear, straight radicles are admirably adapted to recording the rate of growth and other changes. The importance of continuing the investigations with other plants of widely different relationships was nevertheless emphasized.

One experiment was made with water heavily charged with CO_2, in order to ascertain whether the H ions set free by the dissociation of the hypothetical H_7CO_3 might not prove toxic to the radicles. No harmful effect was obtained.

$CaCo_3$ and even $MgCo_3$, added in powdered form to solutions of NaCl and Na_2SO_4, tended to neutralize the injurious effects of those salts. Still more marked was the influence of $CaSO_4$, when added to very toxic solutions of NaCl, in checking the action of the latter.

Solutions of many of those salts, *e. g.*, Na_2Co_3, Na_4SO_4 and CaClr, when of a dilution well below the toxic limit, served as actual stimuli to growth.

O. F. Cook presented a paper on 'The Origin of the Cocoa Nut,' prefacing his remarks with the statement that the origin of many of our domesticated plants was unknown, and in other cases obscure. It was extensively believed that the cocoa nut was a native of Asia and introduced into tropical America, but the speaker showed by quotations from early Spanish writers that it was here at the time of the discovery of America. De Candolle's reasons for and against the American origin of the cocoa palm were critically reviewed and the conclusion reached that the objections to the American origin could be successfully combated.

Attention was drawn to the fact that, contrary to universal belief, the cocoa nut could not withstand exposure to salt water, and that it was not likely that so delicate a palm had received its wide distribution by any other than human agency. Finally Mr. Cook stated his belief that the cocoa palm had its origin in some of the valleys on the western slopes of the Andes and had travelled westward in company with man.

F. A. LUCAS.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

AT the 528th meeting, held January 19th, Mr. L. A. Fischer read 'A Brief History of the Office of Standard Weights and Measures.' He said the office had grown up under the necessity of providing uniform standards of weight and measure for the custom houses. In 1836 copies of these standards were ordered to be furnished to the several States. In 1866 the office was directed to supply copies of metric standards, and still later it has been charged with verifying polariscopes and instruments for electrical measurements.

Mr. A. L. Day, now of the Geological Survey, gave an interesting account of the development, organization and work of 'The Physikalische-Technische Reichsanstalt' of Berlin, in which he was engaged for several years.

Mr. S. W. Stratton, by invitation, spoke on 'The Proposed Standardizing Bureau,' giving a résumé of the plans and of the means taken to bring the subject before Congress, and reading from printed reports some of the arguments made before committees.

CHARLES K. WEAD,
Secretary.

THE LAS VEGAS SCIENCE CLUB.

THE second meeting of the Las Vegas Science Club was held January 8th. Mr. Frank Springer exhibited and commented upon some crinoids from the Burlington Limestone at Lake Valley, New Mexico. He also exhibited and discussed specimens of *Uintacrinus socialis*, Grinnell, which he had found beautifully preserved in the cretaceous of Western Kansas. He showed a number of plates to illustrate a memoir on this species, which will shortly be published in the *Memoirs* of the Museum of Comparative Zoology. The abundance and excellent preservation of the material had permitted him to determine many new facts regarding *Uintacrinus;* and after tabulating the characters of over 600 individuals it became evident that *U. socialis* of America and *U. westfalicus* of Europe were identical, the supposed specific distinctions being due to age and variation.

Mr. E. L. Hewett spoke on the ancient cliff-dwellings and communal buildings of the Pajarito district, New Mexico. He had for some years been engaged in the investigation of these, and presented a map showing their distribution, a number of plans and photographs, and a collection of objects obtained from the dwellings and burial mounds. The communal buildings of the Tchrega, Tsankiwi, Navakwee and Otow; mesas were described; the first of these was estimated to have contained nearly 1,500 rooms, being much larger than the buildings still in use at Taos. Mr. Hewett referred to the importance of preserving these ruins for systematic and careful examination, and the desirability of retaining as public property such important evidences regarding the early man of America as abounded throughout the district. To this end a bill is now pending in Congress, which provided for the retention of the district as a National Park.

T. D. A. C.

NEW YORK SECTION OF THE AMERICAN CHEMICAL SOCIETY.

A STATED meeting was held at the Chemists' Club, 108 West 55th Street, on January 11th, Dr. C. A. Doremus, presiding, and 53 members present.

Dr. Parker reported progress for the Committee appointed to confer with the Bureau of Combustibles in regard to the storage of acids.

The Chair reported that the revision of the By-Laws was in the hands of the Executive Committee in accordance with the action taken at the November meeting. A resolution offered by A. C. Hale was then read as follows:

Resolved, That the New York Section of the American Chemical Society herewith extends a most cordial invitation to the Society to celebrate the 25th anniversary of its foundation next April in New York City, and the Chairman of the New York Section is hereby authorized and directed to appoint such local committees as he may deem expedient in order to aid in perfecting arrangements for such celebration."

The resolution was unanimously approved and the Secretary was instructed to formally extend the invitation to the Society at large.

Dr. T. O'Connor Sloane then read his paper entitled, 'Notes on Spheroidal State Evaporation,' with experiments.

Dr. McMurtrie made a report on the Midwinter meeting just held in Chicago, to the effect that it had been very successful, and the visiting members were well entertained. One hundred and thirty-nine members were registered. Numerous applications for membership in the Society had been entered as a result of the interest aroused.

DURAND WOODMAN,
Secretary.

DISCUSSION AND CORRESPONDENCE.

NOTE ON VEGETO-ELECTRICITY.

IN SCIENCE, September 8, 1900, is an abstract of a paper, by Dr. Waller, on 'The Electrical Effects of Light upon Green Leaves,' which recalls an experience noted in 1888 in my physical laboratory work. In June of that year I asked a student to determine the magnetic elements at a certain place, just under the outer ends of the long branches of a low Norway maple. He reported that the magnetometer was in such continual tremor and slight shifting about that it was impossible to make accurate readings. This continued for hours; and was quite noticeable again some days subsequently

—so that the station was abandoned. This movement was not due to wind, nor to a magnetic storm, nor to any mechanical jarring of the earth.

Except an indefinite item in a newspaper, I have seen no mention of a similar experience.

To determine whether there is from trees such a discharge of electricity as might affect a delicate magnetic needle, I made (in 1895) a coil about 80 cm. diameter of fifty turns of wire, mounted on the end of a long pole, with a contact breaker and a telephone receiver in circuit, and had this coil held in such relation to large, dense limbs of trees as to enclose the lines of magnetic force from a discharge stream (if there be one) of electricity from the limb, selecting limbs in such direction as would make the coil when in proper relation lie in the magnetic meridian plane, determined by simple compass.

April 8th–12th, buds just swelling on deciduous trees, I tried a number of trees, including two or three evergreens. I could hear no disturbance in the telephone, in any position of the coil. Then putting the coil in the magnetic meridian, as explained above, to make the action (if any) stronger than mere variation of discharge, I had the circuit opened and closed. Still there was not the slightest effect perceptible. In the latter half of May, leaves quite fully developed on all except the various oaks, the experiments were repeated with the same negative results.

According to Dr. Waller's experiments, it would have been better to try my experiment in June (when the unexplained action was observed), rather than April and May, the leaves then being in fuller vigor and the temperature higher.

I. Thornton Osmond.

State College, Pa.,
January 21, 1901.

SCIENTIFIC EXPEDITION TO ICELAND, GREENLAND AND LABRADOR.

A geological and geographical excursion in the North Atlantic is planned for the summer of 1901. Conditionally on the formation of a sufficiently large party, a steamer of about 1,000 tons, specially adapted for ice navigation, and capable of accommodating sixty men, will leave Boston on or about June 26th and return to the same point on or about September 20th. The main object of the voyage will be to offer to the members of the excursion party opportunity of studying the volcanic cones and lava-fields, the geysers, ice-caves and glaciers of Iceland, the fiords and glaciers of the west coast of Greenland, and the mountains and fiords of Northern Labrador. Some attention will be paid to the hydrographic conditions of the waters traversed. Botanists, zoologists, ornithologists, mineralogists and those interested in other branches of natural history may pursue independent studies. A hunting party may take part in the expedition; it could be landed for a fortnight or three weeks in Greenland and for about the same period in Labrador.

Explanatory lectures on the regions visited will be given from time to time by the leader of the excursion, who will also act as guide on the Labrador coast where he spent the summer of 1900. It is expected that in Greenland and Iceland, specialists on the geology and physical geography of these countries will lead the party. Wherever possible the attempt will be made to increase the stock of existing information concerning the three regions. It is desirable, though not necessary, that applicants for membership in the party possess at least an elementary knowledge of geology. Citizens of other countries as well as of the United States are invited to participate in the expedition. A physician will accompany the party.

An inclusive fee of $500 for each member will be charged, $250 to be deposited with the leader of the expedition on or before March 15th, the balance to be paid on or before June 1st.

The trip will be under the direction of the writer, and applications for membership should be addressed to him.

R. A. Daly,
Department of Geology and Geography, Harvard University.

CURRENT NOTES ON METEOROLOGY.

REPORT OF THE CHIEF OF THE WEATHER BUREAU.

The 'Report of the Chief of the Weather Bureau for 1900' devotes considerable space to forecasts. The beginning of storm forecasts for

the North Atlantic Ocean is noted, this step being made possible by the use of reports now received from the West Indies, the Bahamas, Bermuda, France, Great Britain, Germany, etc. Whenever possible, forecasts are to be made of wind force and direction for the first three days of the voyage of all outgoing steamships. A brief history of each hurricane that occurred during the year is given, with copies of statements from persons not connected with the Weather Bureau regarding the efficiency of the storm-warning service. An important improvement in connection with the display of storm-warnings for the benefit of mariners has been made by the adoption of a specially constructed steel tower, with a flagpole at its summit. From this pole the signal flags are flown by day, and on it lanterns are displayed at night. 'Eminently satisfactory' progress is reported to have been made with experiments in wireless telegraphy. The importance of the Weather Bureau's Lake Marine service may be understood from the statement that 'each of the 20,000 or more vessels that pass Detroit receives the latest information available with regard to the force and direction of the wind, and the location and probable movement of storms.'

WEST INDIAN HURRICANES.

UNDER the title 'West Indian Hurricanes' the Weather Bureau has issued a report, prepared by Professor E. B. Garriott, which will find many interested readers. Since the United States has come to take an active political interest in West Indian affairs, West Indian hurricanes have assumed an additional importance in the eyes of the American people. This monograph gives a general account of these storms, their laws of circulation, cloud movements, tracks, formation, prognostics and characteristic phenomena. Poëy's table of hurricanes from 1493 to 1855 is given, supplemented by a table based on Weather Bureau records, giving the hurricanes from 1878 to 1900. Then follow brief descriptions, arranged by months, of recent hurricanes, including the famous 'Galveston Storm' of last September, and lastly local descriptions of historic hurricanes. Charts showing the hurricane tracks for each month for the years 1878 to 1900 accompany the report, which is to be recommended as being a readable, non-technical discussion of the subject with which it deals.

MONTHLY WEATHER REVIEW.

THE *Monthly Weather Review* for September (issued November 16th) contains the following articles: 'West Indian Hurricane of September 1–12, 1900,' by Professor E. B. Garriott; 'Special Report on the Galveston Hurricane of September 8, 1900,' by Dr. I. M. Cline, Local Forecast Official at Galveston; 'The Storm Waves of South Carolina and Texas,' by General E. P. Alexander; 'On the Color and Polarization of Blue Sky Light,' by N. E. Dorsey; 'Review of Professor Very's Memoir on Atmospheric Radiation,' by N. E. Dorsey; 'The Frequency of Hail in the United States' and 'The Crop as depending on Meteorological Conditions,' by Professor Cleveland Abbe.

R. DEC. WARD.

BOTANICAL NOTES.

BOTANICAL OPPORTUNITIES IN WASHINGTON.

IT may be doubted whether the botanists of this country fully realize the magnitude of the botanical work now being done in Washington. In the Department of Agriculture there are several 'divisions' devoted wholly to botanical investigations, and several others whose work contributes more or less to the enlargement of our scientific knowledge of plants. Thus the 'divisions' of Botany, Vegetable Physiology and Pathology, and Agrostology are so many divisions of the science of botany, while the 'divisions' of Forestry, Soils, Biological Survey, Experimental Gardens and Grounds, and Pomology, and the 'section' of Seed and Plant Introduction, are more or less contributory to botanical science. All these have much in them which is of interest to the botanist; in fact, some of the most interesting contributions to the scientific aspects of botanical inquiry have come from the second list, where the applications of science are generally emphasized. To these must be added the National Herbarium under control of the Smithsonian Institution, where are stored nearly a million botanical specimens.

With the liberal policy followed by the Secretary of Agriculture and the Regents of the Smithsonian Institution, there are here many opportunities for profitable work along different lines. In spite of the crowded quarters in which all the men in these 'divisions' are compelled to work, they are willing to make room for botanists who wish to study with them. With a little encouragement it is probable that a system of 'tables' will be arranged for the benefit of investigators who wish to take advantage of the collections, libraries, laboratories, and more than all—of the men to be found here. When we remember that there are from thirty-five to forty trained botanists in the government service, we can realize somewhat better what it may mean to most teachers of botany (generally isolated from their kind) when the opportunity is open to spend a couple of months in botanical study in Washington. So also with the lonely experiment-station botanist, puzzling over the problems that come to him, a few months of personal contact with these experienced workers in Washington would be of the greatest service. Without reflecting upon the work of the marine and other aquatic laboratories, it is safe to say that for most botanical teachers and experiment-station botanists a few weeks of study in the 'divisions' in Washington would be of more value.

In this connection it is well to emphasize the fact that the scientific 'divisions' in the Department of Agriculture should have more and better rooms for the trained men who are at work in them, as well as for the preservation of the collections, libraries and laboratories. Congress should not hesitate to grant the moderate sum asked by the Secretary of Agriculture for increased laboratory facilities. Eventually there should be a fire-proof building for the department, so planned that it may furnish adequate laboratory facilities for all the 'divisions,' and complete protection to the priceless collections of specimens and books, at the same time providing for the enlarged uses referred to above.

CENTRAL MASSACHUSETTS FORESTS.

IN an interesting paper in *Rhodora* (Vol I., No. 8), Professor G. E. Stone discusses the forest conditions of central Massachusetts. In the course of his discussion he says: "The characteristic forest trees in this locality are the pine, chestnut, oak and birch. The pine and chestnut are especially adapted to this region, as is shown by their great abundance, both of these being more common in central Massachusetts than in any other portion of the State. The pine is especially abundant here, because of the fact that it can adapt itself to a great variety of conditions." A little later in his paper we find that "the principal forest trees at present are the pine, chestnut, oak, birch, maple, alder, poplar, willow, ironwood, hickory, hemlock, ash, cedar, spruce, beech. Their predominance follows quite closely after the order named. This order is not, however, the same as that which occurred in the primitive forests. The hemlock, beech and canoe birch have decreased, and other species have taken their places. The pine was always, and is to-day a valuable and prominent tree in this region, and undoubtedly is holding its own. The amount of young pines now in central Massachusetts is considerable. There is in fact no tree which takes so readily to the old and neglected pastures as does the pine, and they are gradually becoming filled with this species. This is a most fortunate occurrence, as these old pastures are practically worthless for other purposes, and it is by this means that the pine holds its own so readily, and compensates for that loss which occurs in consequence of rotation with hardwood where forests of this tree have been cleared." Professor Stone concludes from a study of the historical records of the forests that "on the whole, the climatic conditions have probably not changed very much, though undoubtedly local effects have been brought about by the removal of the forests, and also from industrial activities."

CHRYSANTHEMUM RUST.

DR. J. C. ARTHUR, of the Indiana Experiment Station, has given the results (in Bulletin 85) of his experiments on the rust which affects the chrysanthemum. This is a true rust (*Uredineae*), and to it the name of *Puccinia chrysanthemi* has been given (1900) by Roze, a French botanist. It has been known in this country and Europe

for a few years only, but apparently it has been known for a long time in Japan. In order to settle the question whether the rusts affecting other Compositae might give rise to that on the chrysanthemum, Dr. Arthur made many cultures of the rusts on this and other related plants. He found that he could not infect other Compositae with the uredospores of chrysanthemum rust, nor could he infect chrysanthemum with the uredospores of the rusts of other Compositae. No teleutospores have yet been observed in this country or Europe, and this fact is likely to make the disease more easily controllable. Hand-picking the diseased leaves, and spraying with Bordeaux Mixture or sulphide of potassium are recommended.

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

THE NATIONAL OBSERVATORY QUESTION.

THE introduction by Senator Morgan last week of a bill to organize the National Observatory of the United States, of which we have not yet seen a copy, and a letter from Professor Bigelow which we published last week, suggest a condensed statement of the points at issue. The grounds taken by SCIENCE are these:

1. The United States, like every other leading government of the world, should have a national astronomical observatory.

2. The special object of this observatory should be to make those observations and calculations on the courses of the stars which are useful in the world's progress, and require to be pursued with greater system and persistence than is possible in any but a national establishment.

3. This purpose requires that the observatory should have a well understood and well defined policy and plan of work, mapped out by the best scientific authorities at command of the nation and obligatory on the scientific staff.

4. No work but the best should be done; of second-class work an abundance may be had everywhere. This requires that the instruments should be of the best.

5. To attain these purposes it is necessary that the head of the observatory be an experienced astronomer. This because of the high technical skill and experience required in planning the work, in seeing that the innumerable details necessary to its excellence are attended to, and in so expending the funds of the observatory as to get the best results, and also to inspire the confidence of the scientific public in the high quality of the work.

Every effort on the part of our astronomers to get an observatory of this kind established has been defeated through the impression that we already have one which answers the purpose. In the opinion of every astronomer who has publicly expressed views on the subject this is not the case. So far as we are able to collect published views, while there may be much disagreement on side issues, there is absolute unanimity that the existing observatory fails to perform the required functions in a satisfactory way. Yet, we are quite ready to regard the question as an open one until everything that can be said in favor of the work and results of the existing observatory is brought out. If there is a single astronomer in the land who, after a careful examination of the published volumes of the observatory, draws the conclusion that the objects in question have been satisfactorily gained, or, after having read the annual reports of the past five years, concludes that they describe the class and character of work which should be expected from the most expensively supported astronomical observatory in the world, the columns of SCIENCE are cordially thrown open to him to make known his views, and the facts on which those views are based.

It is a well-known fact that our existing observatory is unique in the main feature of its

organization, that of being governed by a head who is not an astronomer and who has no thread of law to guide him in his administration. Another unique feature, without parallel in the history of astronomical observatories, is the misfortunes with its instruments which we pointed out in our first issue of this year. Here our information was based wholly on the official reports, no weight being given to the possibility that the actual condition of the instruments may be a little worse than made known in the public statement. Is it possible to dissociate in the mind of the scientific public these two unique features?

We commend the reading of what Mr. Bigelow has said on the subject, though he is silent on its main points, and the grounds he takes are not at all clear to us. On one point he labors under a misapprehension. If he will re-read our article he will see that we made no charge against the administration in connection with the Magnetic Observatory, but only inquired how it happened that one of the finest magnetic observatories in existence was set-up in the immediate neighborhood of a trolley line, the electric current of which would necessarily be destructive to the results. Mr. Bigelow informs us, as a 'well-known' fact, that this was done by the united counsel of the astronomical director and a prominent visiting English astronomer and against the arguments of the professor in charge of the work, and all others in Washington interested in magnetic observations. He intimates that other interests than those of science prompted the proceedings. We are thankful for this statement, which, if correct and complete, will enable the reader to draw his own conclusions, but we do not know on what ground he says that the fact is 'well known.' It may be well known to those concerned, or to people in Washington generally, but we never before heard or read of it. We may remind Mr. Bigelow that an unnamed 'visiting astronomer' cannot bear a heavy weight of responsibility, and we hope that he will allow this unfortunate counsellor to state his side of the case.

This summary of views, reasons and arguments, seems to exhaust the case in its present aspects, though we may need to return to it when Senator Morgan's bill and the naval appropriation bill are taken up by the Senate. The question is not of concern to astronomers only, but is probably the most important subject at present before American men of science.

SCIENTIFIC NOTES AND NEWS.

M. Fouqué, professor of mineralogy in the Collège de France, assumed the presidency of the Paris Academy of Sciences at the first meeting of the year on January 7th, succeeding M. Michel Lévy. M. Bouquet de la Grye was elected vice-president, and will consequently assume the presidency next year.

Dr. Grabowsky, of the Natural History Museum at Brunswick, has been appointed director of the Zoological Gardens at Breslau.

Mr. E. J. Butler, M.B., has been appointed by the Secretary of State for India, on the recommendation of the director of the Royal Gardens, Kew, to the post of official botanist to the Indian Government at a salary commencing at £600 per annum.

Mr. William Wallace has resigned the position of superintendent of the building of the American Museum of Natural History.

Terrestrial Magnetism reports that Mr. James B. Baylor has now completed the magnetic survey of North Carolina, which has been carried out at the joint expense of the U. S. Coast and Geodetic Survey and the North Carolina Geological Survey. The first report upon this work, prepared by Messrs. Baylor and Hazard, is ready for distribution.

The British Institution of Mechanical Engineers has presented the first Willan's premium to Captain H. Riall Sankey.

LORD RALEIGH has been appointed chairman of a Board of Trade committee to consider the extent to which the working of the traffic on the Central London Railway produces vibration in the adjacent buildings, and what alterations in the conditions of such working or in structure can be devised to remedy the same.

PROFESSOR MANSFIELD MERRIMAN, head of the department of civil engineering, Lehigh University, has issued a circular letter to the County Commissioners throughout the State of Pennsylvania, offering on behalf of the University, to make, without expense to the Commissioners, tests of hydraulic cement to be used on public works. In the report of the results of these tests no opinion will be expressed on the value of the cements.

AT the annual meeting of the Washington Academy of Sciences, on January 17, 1901, the following officers were elected:

Chas. D. Walcott, *President.*

W. H. Holmes, *Vice-President* for the Anthropological Society.

F. A. Lucas, *Vice-President* for the Biological Society.

V. K. Chestnut, *Vice-President* for the Chemical Society.

John A. Kasson, *Vice-President* for the Columbia Historical Society.

H. G. Dyar, *Vice-President* for the Entomological Society.

A. G. Bell, *Vice-President* for the Geographic Society.

G. K. Gilbert, *Vice-President* for the Geological Society.

S. C. Busey, *Vice-President* for the Medical Society.

J. Howard Gore, *Vice-President* for the Philosophical Society.

Frank Baker, *Secretary.*

Bernard R. Green, *Treasurer.*

Managers: Class 1902—L. O. Howard, J. W. Powell, Carroll D. Wright. Class 1903—F. W. Clarke, C. Hart Merriam, Whitman Cross. Class 1904—Marcus Baker, Geo. M. Sternberg, G. M. Kober.

THE Middleton Goldsmith Lecture for 1901, before the New York Pathological Society, will be delivered by Dr. Charles S. Minot on March 26th. The subject announced is 'The Embryological Basis of Pathology.' We learn that it is the lecturer's intention to discuss the general laws governing both the normal and pathological differentiation of cells.

THE Duke of the Abruzzi and Captain Cagni gave before the Italian Geographical Society, on January 14th, accounts of their recent Polar expedition. The King and Queen of Italy and a distinguished audience were present. The freedom of the City of Rome has been conferred on the Duke of the Abruzzi.

PROFESSOR FRANCIS H. HERRICK, of Western Reserve University, delivered an illustrated lecture before the Sigma Xi Society of Yale University on January 19th, on 'The Habits of Wild Birds.'

THE annual meeting of the Neurological Society of London was held on January 24th, when the presidential address was delivered by Dr. W. J. Mickle on 'Mental Wandering.'

PROFESSOR SILVANUS P. THOMPSON gave a lecture on January 10th, at the Urania, in Berlin, on 'Faraday and the English School of Electricians.'

THE Royal Geographical Society of Australasia has established a Thomson Foundation Medal in recognition of Mr. J. P. Thomson's great services to the Society, of which he is regarded as the founder, and which he has served in many capacities. The gold medal is to be awarded annually for the best original contribution to geographical literature, preference being given to the geography of Australasia.

THE annual meeting of the Geographical Association was held in London on January 9th, when Mr. Douglas W. Freshman was elected president and Mr. A. J. Herbertson, vice-president. The membership of the Association is now 134, representing 84 schools and colleges. Plans are being considered for the publication of a geographical journal for teachers of geography.

THE annual meeting of the Board of Regents of the Smithsonian Institution was held on January 23d. The following changes were announced in the membership of the Board: Hon. Richard Olney, to succeed Dr. William Preston Johnston, and Judge Gray of Delaware, to fill the vacancy caused by the death of Dr. William L. Wilson. The vacancy in the executive committee, caused by the death of Dr. Wilson, was filled by the election of Representative

Hitt of Illinois. It was decided in view of the proposed abolition of the English cemetery at Genoa which contains the remains of James Smithson, the founder of the Institution, that the Secretary be requested to arrange with the authorities of some other cemetery, at Genoa, for the re-interment of Mr. Smithson's remains and the transfer of the original monument. It will be remembered that the Smithsonian Institution placed a tablet on Smithson's tomb and that it is properly cared for.

AT a meeting held recently at Colchester it was decided to erect a marble statue of William Gilbert, whose great work, *De Magnete*, published just three hundred years ago, laid the foundation of electrical science. The statue, towards which £130 has been subscribed, is to occupy a niche in the façade of the new town hall of Colchester.

WE regret to learn of the death, at the age of sixty-six years, of Elisha Gray, which occurred on January 21st, from heart disease. Mr. Gray was the author of 'Experimental Researches in Electroharmonic Telegraphy and Telephony' and of 'Elementary Talks on Science,' and is well-known for his important inventions in telegraphy, telephony and electrical appliances.

COLONEL F. F. HILDER, chief clerk of the Bureau of American Ethnology, died of pneumonia at his home in Washington on January 21st, at the age of seventy-four years.

THE death is announced, at the age of thirty-eight years, of Mr. John Henry Leech, the English entomologist. He was the author of numerous works on this science including 'The Butterflies of China, Japan and Corea.' The collections made by him for this work are now partly in the South Kensington Natural History Museum. Mr. Leech was proprietor of *The Entomologist*.

WE also regret to learn from *Nature* that Mr. S. W. Egan, since 1868 connected with the Geological Survey of Ireland, died in Dublin on January 6th; and that Dr. Giulio Pacher, docent in experimental physics in the University of Padua, has died at the age of thirty-three years.

THE will of Oswald Ottendorfer sets aside about $200,000 for public bequests, including $25,000 to the American Museum of Natural History, $20,000 to the Cooper Union for the advancement of science and art, and $20,000 to the New York Free Circulating Library.

THROUGH the liberality of T. M. Baird, Jr., Esq., of Victoria, B. C., a tract of land on the coast of Vancouver Island, opposite Cape Flattery, has been presented for a seaside botanical station of the University of Minnesota. The erection of a group of log buildings has been begun, and a party of thirty or more botanists has been organized to open the work of the station next June.

HALF the educational staff of the Royal Engineering College at Coopers Hill has been summarily dismissed, for the purpose, as it is somewhat oddly stated, of 'reducing the present excessive cost of the staff and increasing the efficiency of the teaching.' The College at Coopers Hill is primarily for the training of students for the public works—telegraphs, railways, etc.—of India, and appears to be under the direction of a military officer with no scientific or educational qualifications and a board of visitors. There is a general protest against this action, Lord Kelvin, for example, having written to the London *Times* as follows:

The correspondence which appeared in the *Times* of Januard 3d regarding Coopers Hill College has caused a painful shock to all who know of the good work which the college has done in giving to India the benefits of well-trained engineers in the service of its Government. No one can read that correspondence, I believe, without being convinced that the seven professors and teachers whose position is threatened are justified in asking for an inquiry.

The proposed action—a sudden and arbitrary dismissal of able and distinguished scientific teachers who have been doing duty for periods of from nine to thirty years in a satisfactory manner—is certainly not to be expected in institutions under the control of the British Government; and I sincerely hope that the Secretary of State for India in Council will see his way to granting the request for an inquiry.

ANOTHER case, in which the appointment of a military officer without scientific attainments as head of a scientific institution has worked unfortunately, is brought to our attention in the case of M. Charles Lagrange, director of the Royal Observatory of Belgium. It appears from the *Independence Belge*, as quoted in *Na-*

ture, that M. Lagrange has resigned his office and has presented to the Belgian Academy of Sciences his two years' arrears of salary, or a capital sum of ten thousand francs, to establish a prize to be awarded, at intervals of four years, for the best contribution to our knowledge of the physics of the globe. In expressing the thanks of the Academy for the gift, General Brialmont described the circumstances which led to M. Lagrange's resignation. It appears that for the past two years the position of director of the Observatory has been a humiliating one, because a young infantry officer, without scientific attainments, has controlled the establishment.

WE are glad to notice that the House of Representatives has, under a suspension of the rules, passed a bill increasing the salary of the Commissioner of Education for Porto Rico from $3,000 to $4,000. If, however, our Government is generous in disposing of the money of the Porto Ricans, it should be just in distributing the greater wealth at its disposal, and the eminent Commissioner of Education for the United States should receive as large a salary as the commissioner for Porto Rico.

MR. STARK has introduced into the House of Representatives a resolution of the Legislature of the State of Nebraska, requesting the passage of the bill for the establishment and maintenance of a school of mines in every State where such does not now exist, which has been referred to the Committee on Public Lands.

AT a recent meeting of the New England Anti-vivisection Society, Joseph L. Greene quoted from Senator Gallinger, of New Hampshire, to the effect that the bill against cruelty to animals in the district of Columbia would probably not be taken up at the present session, because of the pressure of business.

THE German budget for 1901 includes 200,000 Marks for the construction of a laboratory for hydraulic experiments at Berlin. The total cost of the laboratory will be about 365,000 Marks. It will be used by the administrations of the Imperial Marine and Inland Waterways and by the students of the technical school. The budget also provides for non-recurring expenditures on science and art over 6,000,000 Marks.

GREAT interest is being taken in the imminent drying up of Great Salt Lake caused by irrigation. We are informed that the plan suggested by Mr. Marcus E. Jones to build a canal from the headwaters of the Snake river, and thus bring water into the Great Basin to replace the waste by evaporation is meeting with general favor. The Utah Legislature is expected to take up the matter at this session. The agricultural sections of Utah are threatened with disaster unless something is done soon.

UNDER the auspices of the International Aëronautical Committee balloon ascents for meteorological purposes were made on January 10th—in so far as the program was carried out—at London, Bath, Paris, Strasburg, Berlin, St. Petersburg and in Virginia.

WE learn from the *Electrical World* that, at a recent meeting of the Frankfort-on-the-Main Association of Electrical Engineers, Herr Wolff, manager of the local branch of the Allgemeine Elektricitäts-Gesellschaft, showed a new form of Nernst lamp. The necessary initial heating of this lamp is effected by a spiral of platinum embedded in fireproof composition. By means of a switch concealed within the base of the lamp, this spiral is automatically cut out of circuit after the lamp has been rendered sufficiently conductive by the imparted heat.

UNIVERSITY AND EDUCATIONAL NEWS.

YALE UNIVERSITY has received a bequest of $50,000 by the will of Albert E. Kent of Chicago, a graduate in 1853. The money is to be used for the enlargement of the Kent Chemical Laboratory which Mr. Kent gave to the University twenty years ago. Yale University has also received during the week, by the death of Benjamin Douglas Silliman, the oldest alumnus of the University, a sum, said to be $80,000, left by a brother in trust. It is expected that the University will also receive a bequest by the will of Mr. Silliman. Yale University would also receive a trust fund of $500,000, left by T. B. Winthrop, an alumnus, in case neither of his children should survive.

MR. JOHN D. ROCKEFELLER has offered to give $200,000 to Oberlin College, on condition that $300,000 in addition be collected during the year.

THE sum of $25,000 has been collected for Amherst College, making available $75,000 promised by two alumni, Mr. D. Willis James and Mr. C. M. Platt.

MR. H. H. HUNNEWELL, of Wellesley, has given $25,000 to Wellesley College for the department of botany.

THE will of the late Joseph Ricker, of Portland, Maine, provides for the distribution of about $300,000 among charitable, religious and educational societies. Among the bequests are the following: Bowdoin College, $20,000; Bangor Theological Seminary, $25,000; Tuskegee Institute, $2,500, and Bates College, $10,000.

ON January 1, 1901, President Jas. W. Strong had secured gifts and pledges to the endowment fund of Carleton College amounting to $100,000. This secured the conditional gift of $50,000 from Dr. D. K. Pearsons offered a year ago. The college has always given unusual prominence to its scientific courses and has an exceptionally good equipment of scientific apparatus.

A UNIVERSITY for women has been founded in Tokio and is expected to open in 1901. A site and about $120,000 have been donated to it.

THERE will be a second meeting of the Association of Universities in Chicago from February 26th to 28th. Among the snbjects to be discussed are 'Migration among Graduate Students,' 'Examinations for the Doctor's Degree,' 'Fellowships' and 'To what extent should a Candidate for the Doctor's Degree be required to show a Knowledge of Subjects not immediately connected with his Major Subject?'

THE University of California will offer at its next summer session instruction in philosophy, education, history, Latin, Greek, physics, chemistry, botany, mathematics and other departments. A short course for farmers is being planned, in which practical instruction will be given in horticulture, irrigation, dairy husbandry, stock breeding, etc. The following professors from eastern universities will take part in the work: James E. Russell, dean of the Teachers College of Columbia University; John Dewey, professor of philosophy in the University of Chicago; H. Morse Stephens, professor of modern history in Cornell University; James W. Bright, professor of English philology in Johns Hopkins University; Liberty Hyde Bailey, professor of horticulture in Cornell University; and Albert S. Cooke, professor of the English language in Yale University.

C. E. CHADSEY, Ph.D. (Columbia), has been appointed lecturer in the department of education, University of Colorado. He will lecture on sociological topics, etc. P. H. Keyser, M.D., has been appointed instructor in psychopathology in the department of psychology of the same university. Students in the law school are required to take the course, and it is an elective in the medical school.

DR. WM. G. SPILLER has been appointed demonstrator of neuropathology at the University of Pennsylvania, and will conduct an elective course for a limited number of graduates and students for the study of the pathology of the central nervous system and the preparation and examination of microscopic sections.

JOHN M. BUCHER, Ph.D. (Johns Hopkins), has been appointed associate professor of chemistry at Brown University. He recently graduated at Lehigh University and has been instructor in Tufts College. At the same university Mr. W. B. Jacobs has been appointed professor of the science and art of teaching.

JOSEPH S. CHAMBERLAIN, Ph.D. (Johns Hopkins), instructor in chemistry, Oberlin College, has accepted the position of private assistant to Professor Ira Remsen, Johns Hopkins University.

DR. MAX VERWORN, associate professor and assistant in the Physiological Institute in the University at Jena, has been called to an associate professorship of physiology at Göttingen, where he will be director of the Physiological Institute.

DR. H. GOLDSCHMIDT, associate professor of chemistry at Heidelberg, has been called to the University of Christiania.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE ENDOWMENT OF RESEARCH.

Is investigation in the physical sciences now limited by the lack of men or money? In other words, is it limited by the insufficient number of investigators capable and ready to do work of the highest grade, or are they unable to secure the means needed to carry on such work? The income of several funds is available for aiding such investigation. In 1797, Count Rumford gave to the American Academy the sum of $5,000, for awarding gold and silver medals for discoveries in light and heat. Until recently, so little use has been made of its income that this fund now amounts to $58,000. The annual income, which exceeds $2,500, may be used for researches in light and heat. The Elizabeth Thompson fund, amounting to $26,000, according to the last circular issued, may be used for investigations in all departments of science. Seventy-one grants have been made from the income of this fund, generally in sums not exceeding $300. Several funds, held in trust by the National Academy of Sciences, show unexpended balances equal to the income of several years. Thus, at the beginning of the present year, the Henry Draper fund of $6,000 had an unexpended balance of more than $2,000 available for investigations in astronomical physics, and no applications had been received for it. In 1886, the writer attempted to secure the sum of $100,000, the income to be used for

aiding astronomers of all countries in their work. Miss Bruce, in 1890, besides her numerous other gifts to astronomy, gave the sum of $6,000 to be distributed in this way. The 15 donations are described in a circular issued in 1891. Many investigations require such large sums of money that they could not be provided for by such funds as these. On the other hand, a small sum judiciously expended sometimes leads to much larger gifts, and may furnish an observer with an instrument, an assistant, or means for publication. A small gift may thus render available, resources of vastly greater value which would otherwise lead to no useful result. For instance, the writer in 1882 received an appropriation of $500 from the Rumford fund, for an investigation in astronomical photography. Presenting the results of this work to the trustees of the Bache fund, he received an appropriation of $3,000, with which an 8-inch photographic telescope was constructed. Twenty-six thousand photographs have since been taken with this instrument which for many years has been used throughout every clear night at the Arequipa Station of the Harvard College Observatory. The early results were presented to Mrs. Henry Draper, who accordingly had a similar 8-inch telescope constructed. This instrument is used here throughout every clear night, on the northern stars, thus supplementing the work of the Bache telescope. With this instrument, also, 26,000 photographs have been obtained. The early results of the Henry Draper Memorial led to the transfer of the Boyden fund, exceeding $200,000, to the Harvard College Observatory, and also to the gift of $50,000 by Miss C. W. Bruce, with which a 24-inch telescope, now successfully at work in Arequipa, was constructed. The results attained by each gift thus helped to secure the next. Again, an appropriation of $500 from the Rumford fund, in 1899, enabled the Directors of the Yerkes, Lick, McCormick and Harvard observatories to cooperate, so that telescopes of 40, 36, 26, 15, and 12 inches aperture are now being used in the same research on the light of very faint stars. The value of the plant utilized in this research exceeds a million dollars. It is hoped that similar cooperation can be secured in continuous observations of the variable stars of long period. In many cases an award of a small sum to an observatory will assure its friends of the value of the work and thus encourage them to contribute liberally. It is believed by the writer that the real difficulty lies in the lack of knowledge of what funds are available, diffidence in presenting applications, and in some cases objection to the restrictions under which the grants may be made. Could these difficulties be remedied by a permanent committee, and if so, how should it be appointed? In no country have such sums of money been given to science as in the United States; in fact, the success so far attained and our future prospects for research depend largely upon such gifts. It is believed that in many cases wealthy men and women would gladly aid scientific investigation if they could be sure that their gifts would be judiciously and economically expended. It is, therefore, of the greatest importance to all scientific men, not only to secure aid for important researches, but to prevent, if possible, the unwise or wasteful expenditure of such money. The writer desires to learn the views of others on this matter, either through the columns of Science, or by personal correspondence.

Edward C. Pickering.

Cambridge, Mass., January 25, 1901.

*RESEARCH WORK FOR PHYSICS TEACHERS.**

The teaching of physics is in itself a delightful thing, but to be thoroughly enjoyed

* An abstract of a paper read before the Physics Club of New York, December, 1900.

it should be plentifully seasoned with research. Science in the past has been indebted in a very great measure for its progress to the teaching class. An inquiry into the statistics of this subject, which I had occasion to make some years ago, and in which I attempted to classify the professions of all the authors up to the middle of the present century, who are sufficiently known to have found a place in the pages of Poggendorff's Dictionary, showed that nearly 90 per cent. of the scientific work of the world had been done by teachers. The remainder was divided almost equally between the members of the medical profession and the clergy. Law was found to be almost entirely unrepresented, the most notable instance of a lawyer who has left a name in science being that of Bacon. There has been of course a considerable number of amateurs in science, and the list contains some famous names, such, in physics, for examples, as Joule in England, and Holtz, Elster and Geitel in Germany; but taken numerically this class shows a very small percentage in the tables. Great as the attainments of the teacher in investigation have been when compared with those of the remainder of the community, the statistics show that in this country at least not more than ten per cent. even of college men engaged in the teaching of physics can be counted as belonging to the ranks of the producers. I have been unable to extend the inquiry to physics teachers in secondary schools, not through any difficulty in enumerating those whose names appear in scientific authorship, but through ignorance as to the total number who are engaged in teaching the subject in the United States. It is clear, however, that the ratio would be even smaller than in the case of those who are teaching in our colleges and universities.

That there are very great and very real difficulties any one who has attempted to carry on research and teaching at the same time must admit. The principal excuses offered for the abandonment of any attempt at scientific performance are *lack of time, lack of apparatus* and *lack of the necessary qualifications for the work.* A comparison of college teachers with the teachers in the secondary schools in these respects has led me to the opinion that the differences of opportunity are much smaller than is commonly supposed. Science teachers, both in the college and in the school, are unquestionably overworked. The tax upon the nervous system of the proper teaching of science is very great, and it is more often the want of surplus energy with which to carry on investigation, than lack of actual time or of the necessary equipment that defeats us. The actual number of hours demanded of teachers is small as compared with that required by many other callings; so much so, that by the outsider the teacher is apt to be regarded as belonging to the leisure class; but measured in terms of vital energy those hours, as we all know, are quite long enough.

The plea of lack of qualification for research is one which the college man feels less free to make than does the teacher in the secondary schools; because he knows that whether he has such qualifications or not he is at least supposed to possess them; whereas it has not yet been demanded of secondary school teachers that they should be capable of actual scientific productiveness. This difference of standard I believe is a false one and most unfortunate; for it is certainly more difficult to teach successfully the beginnings of a subject than to conduct advanced work. The real explanation of the comparative unproductiveness of secondary school teachers lies, I am convinced, in the absence of *the habit of investigation,* a habit which like all others must be acquired by practise and maintained by continued practise. Research flourishes

only in a certain atmosphere, and this atmosphere is to be found only where scientific work is going on. Some little corner of time can always be found even by some of the most overburdened of us, and as to equipment, it should not be forgotten that the scientific appliances at command of the school teacher of the present day are greatly superior to those of the average college man of a generation ago, and are not greatly behind those of the average college man of the present. Yet there was great scientific activity in certain localities at a time when laboratories, as we know them, had not yet come into existence. Men are still living who can remember when the first chemical laboratory in Germany was established by Liebig, and one need not to be very old to look back upon the beginnings of laboratory instruction in this country.

Qualification for research must always be acquired by individual effort. Any one who is really fit to teach science has at least the latent gift necessary to the investigator. To develop the gift he must, however, cultivate the habit of scientific reading and the habit of experimentation. The number of science journals is now so great that no one can longer pretend to read them all; but we have in the admirable summary entitled, *Science Abstracts*, and in *Wiedemann's Beiblätter*, the results of the whole world of physics presented in brief form. One of these two journals should be taken by every physics teacher, and in addition he should subscribe to and read some one of the standard journals devoted to his subject.

Given a well-developed habit of experimentation, it only remains to select some topic and to study that persistently to the point of obtaining definite results before taking up another. All subjects for investigation are not equally within the reach of the teacher in the secondary schools. We can not, for example, expect to duplicate in our laboratories the thousands of storage cells necessary to the carrying on of the researches upon which Professor Trowbridge, of Harvard University, is engaged, nor to lay out large sums for apparatus of any other kind. As a rule, the apparatus necessary to an investigation is, however, not very expensive; certain standard instruments, such as the balance, the thermometer, the spectroscope and the galvanometer, are to be found in every decently equipped school at the present day, and work of the highest interest can be done by supplementing these with special apparatus which may be either home-made or may be obtained at a small cost by employing our ordinary artisans.

The following suggestions of topics for research which may be pursued without elaborate or unusual apparatus in the spare time of any one who possesses the intense love of experimentation, characteristic of the true man of science, may serve to show that there is no lack of material within the reach of every ambitious physics teacher.

The temperature at which pure water reaches its maximum density has been carefully determined, and it is known that the introduction of a gas such as ammonia, which is largely absorbed by water, or of a salt in solution like sodium chloride, or of alcohol or sulphuric acid, not only lowers the freezing point and changes the density of the liquid, but that the point of maximum density falls, as the amount of added substance is increased, more rapidly than the freezing point itself; until finally the phenomenon of maximum density disappears altogether. Any one who possesses a good thermometer reading to low temperatures or who has sufficient skill and experience to make and calibrate a thermo-junction can readily extend this investigation to solutions and mixtures not yet studied. The only instruments required for such investigation, aside from the usual laboratory utensils, are a good thermometer and a

Fahrenheit hydrometer, or a hydrometer of the variable immersion type with the diameter of the neck reduced to the least practicable size. The work is of sufficient delicacy to tax the manipulative skill of the observer, and the investigation is on this account worth the doing simply as practise work, while the results of a careful study of the subject would be welcomed by any of our standard journals of physics. By a similar method, studies may be made of the density and coefficient of expansion of liquids having low freezing points, such as alcohol, ether and carbon disulphide. Something has been done in this line, but the subject is far from being exhausted. By the use of liquid carbon dioxide and ether one can readily reach the temperature —80° C., and it is probable that the time is near when liquid air will be available for the extension of such work to much lower temperatures. Data upon subjects such as these are useful even though no startlingly new phenomena be brought to light, and the observer has before him the possibility of discovering new and important relations which may have a bearing upon our theories of the nature of matter. The verification through this extended range of temperatures, viz., from —80°, and ultimately from —200°, upwards, the law already theoretically established by Van der Waals* for the relation of the expansion of liquids to their critical temperatures; or, failing in that, the experimental demonstration of the necessity of a modification of the theory, would be in itself ample incentive for the investigation.

The subject of specific heats at low temperatures is still awaiting the attention of our experimental physicists. H. F. Weber† a quarter of a century ago studied boron and silicon, in this respect, down to —40° C. and carbon to —50° C., with most interesting results, after which comparatively little was done until 1898, when Behn* obtained values for several metals down to —200°. The specific heat of a great variety of solids and liquids still remains to be determined through the greater range of temperatures now within our reach, and the calorimetric observations are no more difficult nor elaborate at low than at high temperatures. Any one who can set up and calibrate a Bunsen ice calorimeter is in position to make the measurements. A cylinder of carbon dioxide and a can of ether will give refrigeration to —80° C. and perhaps by the time the work for this range of temperatures is completed it may be possible to order a gallon of liquid air by telephone at a reasonable cost and thus readily extend the research to —200° C. Temperature measurements are best made in such work by finding the change of resistance in a coil of fine copper wire.

What I have attempted to point out, in a fragmentary way in the case of two or three particular problems is true of the whole domain of physics. No research is ever complete. However exhaustive it may at first sight appear, it will, when critically considered, be found to afford merely a starting point from which to push further out into the infinite region of the unknown which lies beyond the boundaries of our present knowledge. Every theoretical discussion is based upon assumptions which must be tested experimentally, and such tests usually lead to new and more accurate knowledge of the properties of matter and ultimately to modifications of the theory. Thus Poisson, long since, pointed out that the numerical value of the ratio for the relative contraction of the diameter of a stretched rod to the elongation would be one-fourth for all substances for which the assumption

* Van der Waals, 'Continuität des gasförmingen und flüssigen Zuständes.' Leipzig, 1881.

† H. F. Weber, *Poggendorff's Annalen*, 154, pp. 367 (1875).

* Behn, *Wiedemann's Annalen*, 66, pp. 237 (1898).

made in his theory of elasticity holds true. Measurements, however, showed widely varying values for Poisson's ratio and led to important modifications of the theory. All this may be thought to belong to the ancient history of the science, but to-day, after nearly half a century, exact data are known for only a few substances. I do not mention this as one of the determinations especially adapted to the secondary school laboratory. The quantity to be observed is, of course, exceedingly small. Still the method by which I am accustomed to illustrate the phenomenon to my classes; that of stretching a glass tube filled with mercury and noting the fall of the liquid in the very fine capillary neck gives a good result with glass, and would probably be adaptable without serious difficulties to such other materials as can be obtained in the form of tubes. With the interferometer, direct measurements of the change of diameter ought to be readily made but this instrument is at present not a part of our school equipments.

Another field of work which is easily opened to physics teachers in our secondary schools is that of the study of flame temperatures. The temperatures of the Bunsen burner, the ordinary luminous gas flame, the candle flame and the acetylene flame are already pretty well established, although many important details which are capable of being worked out by a patient observer are still lacking. When it comes to the question of other flames than these, we have only the wildest estimates based upon measurements made by methods, the inadequacy of which has been abundantly demonstrated. The flames of alcohol, of ether and of carbon disulphide burning in air would afford subjects for an interesting and profitable study during one's leisure hours. The apparatus needed for such a research consists of a fairly sensitive galvanometer, a resistance box and a standard cell, together with about one meter each of platinum and platinum-rhodium wire. The obstacles to even approximately accurate high temperature work have until recently been almost insuperable on account of the difficulty of calibrating the thermo-element used; but I have shown in a recent paper * how the very elaborate and laborious methods of calibration hitherto employed by those engaged in such work may be avoided without loss of accuracy and how by the ingenious method first employed by Waggener † in the study of the Bunsen burner, and subsequently by myself for the measurement of the acetylene flame, the heat losses in the thermo-junction which had vitiated the results of earlier observers may be eliminated.

We physics teachers have amused ourselves at one time or another, like many other people, with photography, and a few of us, doubtless, deserve to be classed as experts in the fascinating art. Herein lies a double opportunity for research; in the further development of the science which underlies photographic processes and in the application of the photographic method to the numerous problems in physics to which it is especially adapted. Consider, for example, in illustration of the former, the fruitful field of inquiry suggested by Professor Nipher's ‡ recent memoir upon the action of light and of the X-rays on previously exposed plates, and of the latter the countless investigations of recent years in which the photographic plate has been utilized for recording and studying the phenomena of our science.

By means of a camera containing a revolving drum, upon which a piece of the flexible film used in the making of ani-

† Waggener, *Wiedemann's Annalen*, Vol. LVIII., p. 579.

‡ Nipher, *Transactions of the St. Louis Academy of Sciences* (1900).

mated pictures may be mounted, a great variety of interesting work may be performed. Professor Merritt* and I have shown in a recent paper that very beautiful photographs of the manometric flame are obtainable with the aid of such an instrument, and Professor Hallock has made use of a similar method in an extended analysis of the human voice. Any one who has the patience to systematically study and interpret records of this sort, might add greatly to our knowledge of the physics of articulate speech. With the same instrument the motions of vibrating strings and rods and the decadence of overtones with the time may be studied. The instrument is, indeed, applicable to a very great variety of short-time phenomena, such, for example as the duration of exposure obtained by various flash powders, a subject of which at present our knowledge is very incomplete.

Still another interesting line of work within the reach of physics teachers in our secondary schools consists of the photography of the infra-red spectrum. Becquerel showed many years ago that the fluorescence of calcium sulphide and other substances could be checked and almost annihilated by the long waves of the spectrum, and Fomm, a student of von Lommel, in 1890 succeeded in photographing the infra-red spectrum of the sun by placing a fluorescent screen in the spectral image and subsequently making a contact print by laying the screen face to face with an ordinary sensitive dry plate. In this way he was able to identify and determine the wave lengths of numerous dark lines in the spectrum. The absorption spectra of chlorophyll, of water, of the salts of didymium, samarium, erbium and of other substances which possess well-marked bands in the visible spectrum, have been mapped in this way by Becquerel, but his work should be repeated since his estimation of wave-lengths is known to be entirely at fault. The number of substances as yet untested is very great and the accurate investigation of them might lead to results of high importance. The method of direct photography by means of plates sensitized for the infra-red is probably to be preferred for such work, to the troublesome use of the fluorescent screen.

Finally, not to extend this list of feasible experiments further, permit me to remind my fellow teachers of physics that we have in the spectro-photometer, an instrument by means of which one may investigate visible radiation, reflecting power and the transmission of light, by all sorts of substances. It is a great convenience in such work to have at hand the very perfect modern instruments designed by Lummer and Brodhun or by Brace. I am aware that none of our school laboratories are likely to contain such apparatus; but it is only necessary to purchase a Vierordt slit and to adapt the same to any good ordinary spectroscope in order to be in position to do good spectro-photometric work.

I have attempted in this paper to mention only a few of the numerous topics of research available for physics teachers. It is one of the characteristics of our science, that every contribution to our knowledge brings with it a group of further problems to be solved. One can not read intelligently any memoir describing experimental work without perceiving the possibility of extending the investigation further. The one essential requisite to the carrying out of the suggestions thus received is that burning desire to try things for one's self which characterizes the investigator. Such a desire is the fruit of that habit of experimentation to which I have already referred, a habit which I deem it the first duty of every one, who has the ambition to lay claim to the title of man of science, to foster and

*Nichols and Merritt, *Physical Review*, Vol. VII., p. 93.

cultivate. Given this desire for research, which is the inevitable result of the habit of experimentation in every one whose mind is fit for scientific pursuits, and all other difficulties, those of time, opportunity and equipment can be overcome. Certain lines of investigation which one would gladly follow must indeed be abandoned for lack of means with which to pursue them; but he who keeps alive his knowledge of scientific progress by the systematic reading of the literature of first sources need never lack topics of research.

The proper stimulus for scientific work is the love of experimentation for its own sake rather than any desire or expectation of fame; the delight of witnessing the wonderful performances of matter under conditions conceived and imposed by ourselves, rather than the hope of achieving some momentous result. At the same time we should not forget that the very simplest phenomenon of nature is worthy of our closest, even of our reverent attention and that some experiment as seemingly unimportant as the shooting of quartz fibers, may, like that now famous operation of a fellow teacher (Boys), be ultimately of inestimable value to science.

ON ECLIPSE PHOTOGRAPHY.

Some months ago the writer suggested that the dangers of over-exposure in photographing eclipses might be avoided by a long exposure covering the entire totality of the eclipse, and a development of the plate as a positive in the light. Since that time the interval of exposure in the camera has been considerably reduced by increasing the illumination of the plate while in the developing bath. Plates can with proper exposure be developed in direct sunlight, with a reflected beam of sunlight also thrown down upon the plate. But while such pictures leave nothing to be desired for clearness and sharpness of detail, they do not show any details which can not be brought out in a negative. Moreover, the exposure required to produce a good positive is still rather too long to make this method in its present condition seem of much advantage in eclipse work.

But it has also been found that the developer best suited to producing fine positives will develop beautiful negatives in the dark-room, on plates that have been over-exposed as much as two thousand times. Such plates thus exposed may be developed either as negatives in a perfectly dark room, or as equally good positives in a light room, and with the same developer. Where the normal camera time is a tenth of a second, the exposure may be as great as three minutes and a half, and still secure a sharp crisp negative. With greater exposures it is better to develop the plate as a positive in the light room.

The developer recommended, as the best so far tried, is hydrochinone made up according to Cramer's formula, with the bromide left out. The sodium carbonate solution may be made up at half the strength given in the formula if the developing is to go on slowly. To half an ounce of the mixture of solutions one and two, add an ounce and a half of water and four or five drops of saturated hypo solution.

When the plate has been normally exposed and it is treated with this developer containing two drops of hypo, in a covered tray in the dark room, nothing will develop for 30 or 40 minutes. But in course of an hour and a half the picture will be fully developed. The details will show sharply through the film. The tray should be uncovered as little as possible. The plate is sensitive even to red light. Until the last stages of development are reached, the exposures for examination of the plate

should be as infrequent and as brief as possible.

A Cramer 'crown' plate placed in a printing frame under a thin or fast printing positive, will yield a negative picture when held for one second at a distance of three meters from a 16-candle incandescent lamp. The exposure may be gradually increased to an exposure of an hour at a distance of one meter from a 300-candle Packard incandescent lamp. How much longer the exposure may be is not yet known. All exposures up to three and a half minutes at a distance of one meter from the 300-candle lamp can be developed as fine negatives in the dark room. This last exposure may also be developed as a positive in light somewhat feebler than direct midwinter sunlight in St. Louis. With greater exposures, the illumination of the light room must be decreased, in order to obtain the best results. With the highest exposures producing developable results, the plate must be developed in the dark room.

The actinic values over this vast range are now being measured. The plates as developed are laid in proper position upon a series of large tables, about 40 feet in length. The coordinate values determining the position of the plate upon the tables are, exposure and illumination of the developing room.

The point which it is desired to urge in this communication is, that in the coming eclipses of this year and next, there is no need of losing any plates from over-exposure, even if they are exposed during the entire time of totality. It is hoped that this communication will cause those who are to take part in that work to lose no time in becoming familiar with the possibilities of development in a bath such as has been here described.

This communication has been prematurely published in order to direct the attention of those who are to take part in the observations of the next eclipse to a matter which may have great importance. It may be that some of the statements may require modification. For example, it is perhaps questionable whether exposure in a printing frame at a distance of a meter from a 300-candle lamp for three and a half minutes is an over-exposure of 2,000 times.* It is certainly a very great over-exposure.

FRANCIS E. NIPHER.
WASHINGTON UNIVERSITY.

*Since writing the above it has been found that potassium bromide will do all that has been done with hypo as above described. The earlier failures in the use of bromide were due to insufficient quantity. In developing some good pictures near the zero condition a ten-per-cent. solution of bromide has formed a sixth of the bath. The bromide pictures are somewhat more brilliant, but do not seem so sharp and hard as some obtained by hypo. It may safely be stated that any camera exposure, from the shortest possible, to those lasting for hours, may be developed into a good picture. When the exposure is too great for development in the dark room as negatives, the plate may be as successfully treated in the light room and developed as a positive. A plate which will develop as a beautiful positive in the light of a 16-candle lamp, will develop a foggy mongrel picture, partly positive and partly negative in a perfectly dark room.

THE PROBABLE SUCCESSORS OF CERTAIN NORTH AMERICAN PRIMATES.

THE credit for the discovery of the affinities of the fossil Primates of the Eocene deposits of this country have been variously claimed by both Marsh and Cope. Leidy, however, appears to have clearly preceded both these investigators in this respect in his 'Vertebrate Fauna of the Territories,' published in 1873. In this work, in describing the lower jaw of *Northarctus tenebrosus*, a fossil monkey from the Bridger Eocene, he makes the following significant remarks: "In many respects the lower jaw of *Northarctus* resembles that of some of the existing American monkeys quite as much as it does that of any of the living pachyderms. *Northarctus* agrees with most

of the American monkeys in the union of the rami of the jaw at the symphysis, in the small size of the condyle, in the crowded condition of the teeth, and in the number of the incisors, canines and true molars which are also nearly alike in constitution. *Northarctus* possesses one more premolar and the others have a pair of fangs. The resemblance is so close that but little change would be necessary to evolve from the jaw and teeth of *Northarctus* that of a modern monkey. The same condition which would lead to the suppression of the first premolar, in continuance would reduce the fangs of the other premolars to a single one. This change with a concomitant shortening and increase in the depth of the jaw would give the characters of a living Cebus."

In studying the rich collections of this Primate material in the Yale Museum, I have been forcibly struck with the accuracy and wisdom of Leidy's comparison. Not only does it appear to me that there is a decided resemblance between these extinct North American forms and the living South American Cebidæ, but I am firmly of the opinion that the one was the direct descendant of the other. This proposition I find is sustained by a number of trenchant osteological facts which I hope to fully elucidate in my forthcoming publication on the subject.

While they may in general be said to be in a corresponding stage of evolution to that of the living Lemurs, they nevertheless belong to a separate and distinct phylum. This phylum detached itself from the main Primate stem far back in early Tertiary time. When the tropical forests receded to the southward of the land bridge which connected Asia with North America during practically the whole of the Tertiary, the interchange of species which were dependent upon this tropical vegetation was no longer possible, and at this point began the development of the two phyla, one of which terminated in the Old World monkeys and man and the other the flat-nosed monkeys of the New World.

In the earlier half of the Middle Eocene or Wasatch these monkeys were abundant in northern Wyoming. During the deposition of the Bridger beds or first stage of the Upper Eocene, we find them in southern Wyoming, where they may be said to have reached their culmination, so far, at least, as numbers and variety are concerned. We are at liberty to infer from much collateral evidence that this region was at that time intensely tropical and was highly suited to their manner of life, since some of the more common species are represented by remains of thousands of individuals in the collections. Towards the close of the Bridger, however, premonitions of the coming changes began to make themselves felt, probably first in the altered character of the vegetation. These were of such a nature as to cause another retreat to the southward, which must have been more rapid, since in the succeeding Unita or uppermost Eocene stage we find but a few stragglers of the hardier and more abundant species left behind. Such, however, soon disappear, and with this record, so far, at least, as our knowledge at present extends, their history on the North American continent closes. It is a highly significant fact that in the succeeding Oligocene and Miocene deposits the remains of monkeys are wholly absent, in the northern latitudes, at least, where they were formerly so abundant. The only conclusion we can draw from this is that the tropical vegetation had receded to the south, and taken with it all the inhabitants dependent upon it.

We next hear of these Primates in the Miocene beds of Patagonia, showing clearly that they had not only reached the South American continent at that time in their southward peregrinations, but that they had spread themselves quite to its extreme south-

ernmost limits. This fact argues strongly for a pre-Miocene land bridge between North and South America, just as the North American ancestry of the Edentata, as I have already pointed out, calls for a similar explanation. Had the conditions been favorable, and the southern barriers been sufficient to arrest further progress, we could believe that through stress of environment a much higher type of monkey, and possibly a man, might have been evolved in the Western Hemisphere in the manner so ingeniously suggested by Duncan. But as it is the Cebidæ represent the highest expression of Simian development which has ever been attained on this continent.

J. L. WORTMAN.

YALE UNIVERSITY MUSEUM,
January 23, 1901.

AMERICAN PSYCHOLOGICAL ASSOCIATION.

THE ninth annual meeting of the Association was held in Baltimore, December 27 and 28, 1900, in affiliation with the American Society of Naturalists. The President of the Association, Professor Joseph Jastrow, was in the chair, and on the afternoon of the 27th delivered the presidential address. At the business meeting held the same afternoon, Professor Josiah Royce was elected President of the Association for the ensuing year, and Professors J. Mark Baldwin and John Dewey were elected members of the Council for terms of three years. Several matters of interest were discussed at the business meeting. An invitation from President Harper to hold the next annual meeting at the University of Chicago was received and after full discussion it was voted unanimously that the invitation be accepted, power being given to the Council to arrange for the meeting.

A committee of five was appointed to consider the question of undertaking in part the publication of Dr. J. H. Leuba's proposed catalogue of psychological literature and to report at the next meeting of the Association.

A resolution was adopted that the Committees of Arrangements of Foreign Congresses of Psychology be requested to confer with the American Psychological Association with regard to the American representation at such congresses and the participation of American members in their proceedings.

Sessions for the reading of papers were held on the morning of the 27th and on both the morning and the afternoon of the 28th.

Professor Jastrow's presidential address was upon 'Currents and Undercurrents in Psychology.'* The speaker took up in turn various aspects of modern psychology. After discussing the significance of the evolutionary conception of the science, he spoke of the three-fold mode of approach, viz., the genetic, the normal and the abnormal, to many of its problems as being productive of interesting and valuable advance, and outlined the advantages and limitations of each aspect. The contemporary interest in certain functional complexes, notably reading and writing was noticed and the whole question of the practical bearing of psychology was discussed, the speaker assuming a conservative position in the matter.

At the first session on Thursday morning, Mr. Robert M. Yerkes, of Harvard, read a paper on 'Habit Formation and Memory in Invertebrates and Lower Vertebrates.' This was a preliminary report of some experimental studies in animal psychology now being conducted in the Harvard Laboratory. The chief purposes of the work are (1) to determine to what extent, with what rapidity, and precisely how, animals learn; (2) to test the permanency of any associations formed and (3) to make as many supplementary observations on the

*Published in full in the *Psychological Review* for January, 1901.

general habits and reactions of the animals used as possible. The labyrinth method, in various forms, has been used for all the work. Observations have thus far been made on the crayfish, green crab, fiddler crab, newt, frog and turtle. Crayfish in a simple labyrinth, involving choice of direction only once, improve rapidly from fifty per cent. correct in the first ten trials to ninety per cent. correct in the sixth ten. There is evidence of the habit (*i. e.*, memory) after two weeks' rest. Newts, judging from these studies, learn very slowly and there is successive variability among individuals. Frogs alone, of the animals named, have shown the formation of a habit as the result of a single experience. Turtles are very apt in the formation of labyrinth habits, and retain them for weeks. They give a curve of learning very similar to those of the cat and dog. In all the experiments record is kept of the time taken to escape from the labyrinth and of the course followed.

This paper was succeeded by one by Dr. Shepherd Ivory Franz, of the Harvard Medical School on 'Frontal Lobes and Association.' The experiments were undertaken to determine whether or not the frontal lobes in animals are concerned in the production of certain sensory-motor associations. Cats were given the opportunity of learning simple habits, after the learning of which the frontal area anterior to the crucial sulcus was excised. After the operation the habits previously learned were lost. A series of control experiments shows that this result cannot be accounted for on the supposition of surgical shock. The conclusion was drawn that the frontal lobes are *normally* concerned in the formation of these habits. The animals that had thus acquired and lost certain associations were found to have the ability for re-learning these habits and for acquiring new ones. This ability (re-learning) may be due to the use of other association areas (either the parietal or the occipito-temporal lobes), but the evidence is not yet complete.

Dr. R. S. Woodworth and Dr. E. L. Thorndike reported the results of the continuation of their experiments on 'The Influence of Special Training on General Ability.' The following conclusions seem to them justifiable:

The mind is, on its dynamic side a machine for making particular reactions to particular situations. It works in great detail, adapting itself to the special data of which it has had experience. Change in the time or precision or quality of any one of these particular reactions need not and often does not influence appreciably other reactions, similar enough to be called by the same name. Change in any one almost never brings about an equal change in any other reaction, no matter how similar, for the working of every mental function is conditioned by the nature of the data on which the function is employed. The amount of influence of changes in any one mental function upon others is much less than has been supposed. The cases of such influence and of its absence make it seem probable that change in one function affects others only where and in so far as identical elements are present in both. By identical elements are meant concrete elements, such as sensations, images, movements, etc., the actual content of which is identical.

Professor J. McK. Cattell reported on 'Psychological Tests of Abnormal and Exceptional Individuals.' Attention was called to the desirability of extending physical and mental tests to those suffering from disabilities and disease on the one hand, and to those showing exceptional aptitudes on the other. A description was given of cases of nervous disease tested by the speaker, and it was shown how these differed from normal individuals and how far the nature and

progress of the disease could be deduced from such tests. Turning to an exceptional case, similar tests made on the chess player, Mr. Pillsbury, were described. The speaker also noted the correlation of the tests made on the freshmen and seniors of Columbia College, mentioned tests made on the cleverest and dullest children in a primary and in a high school, and described a photographic method of measuring the features.

The last paper of the morning, by Professor E. F. Buchner, on 'Volition and Experiment,' was read by title.

On Friday morning Professor Edward A. Pace presented 'A Note on Binocular Rivalry.' The purpose of the experiments was to determine whether the fluctuation of retinal fields is influenced by such mental factors as expectation and recognition. It was found that when the fields (colored squares or figures) are presented in succession, the new field dominates in consciousness. The mere fact that one field is familiar and the other strange does not affect the result. Efforts of the will to retain a field when a new stimulus is applied to the other retina are not at first successful. By repetition, however, control is gradually acquired, so that, in proportion as the novelty of the intruding field wears off, inhibition becomes easier.

Professor Charles H. Judd followed with a paper, 'The Analysis of Writing Movements.' The method consists in attaching a tracer to the hand in such a way that it will not be affected by the fingers, but will record any movement of the hand as a whole. If one writes with such a tracer attached to the hand, the written letters will contain the finger components as well as hand and arm movements, while the tracer record will not contain the finger components. Apparatus and records were exhibited to illustrate the method. It is found that the hand and arm do not participate in the finer formative parts of the writing movement, but merely carry the fingers forward, thus contributing the grosser elements, especially those in a forward direction. Marked differences appear in the modes of coordination employed by different individuals.

Professor J. A. Bergström demonstrated an ergograph and reported studies made with the instrument.

Dr. Arthur MacDonald spoke on the susceptibility to disease and physical development in college women, the data on which his statistics were based having been furnished by the professor of physical culture and the resident physician in one of our woman's colleges.

Dr. E. W. Scripture described further experiments on rhythm made in the Yale Laboratory and Professor E. C. Sanford spoke briefly of some new apparatus.

In the Philosophical Section of the Association, which held meetings both in the morning and in the afternoon of Friday, Mr. Henry Rutgers Marshall spoke on 'Self-consciousness and its Physical Correlate.' If each special mental state in a given individual corresponds with a differentiation of process in that individual's nervous system, then 'self-consciousness' must have coincident with it some special form of neural activity. The neural process in man is the activity of an enormously complex neural system which itself is made up of minor neural systems: consciousness then, under this hypothesis, must be looked upon as a vast psychic system made up of minor psychic systems. System as a whole, any increment of activity in any minor system will stand in contrast with the mass of activity of the complex system as a whole. The most ordinary presentations to the Self correspond with such special increments of neural activity; hence we are led to ask whether the Self may not be that part of consciousness which corresponds with the mass of psychic activity in the complex neural system as a whole.

Mrs. Christine Ladd Franklin read a paper on the 'Reduction to Absurdity of the Ordinary Treatment of the Syllogism,' which will be published in SCIENCE. Other papers in the philosophical section were 'The Kantian Doctrine of Space,' by Professor George S. Fullerton; 'Nietzsche,' by Professor Grace Neal Dolson; 'Professor Ladd's Theory of Reality,' by Professor William Caldwell; 'The Doctrine of the Two-fold Truth,' by Professor F. C. French; 'A Study of Pluralism,' by Professor A. H. Lloyd; 'The Problem of an Emotional Logic,' by Professor W. M. Urban; 'Examination of Professor Sidgwick's Proof of Utilitarianism,' by Dr. Ernest Albee 'A Peripatetic Formula for the Moral Ideal,' by Professor W. R. Newbold; 'Active and Passive Reason in the Writings of Aristotle,' by Professor W. A. Hammond. The last named paper was read by title.

LIVINGSTON FARRAND.
COLUMBIA UNIVERSITY.

IOWA ACADEMY OF SCIENCES.

THE fifteenth annual meeting of the Academy met in Des Moines, Iowa, on December 26, 27, 28, 1900. A lengthy and an excellent program was carried out. The annual semi-popular lecture was given by Dr. Wm. Trelease, of the Missouri Botanical Garden, on the 'Harriman Alaska Expedition' on Thursday evening to a large and highly appreciative audience. The president, Professor W. H. Norton, delivered his presidential address on the 'Social Service of Science' on Wednesday evening. Professor Norton sketched briefly the service of science to society. This service is not appreciated as it should be, and yet nearly every modern convenience in the industrial world had its origin in the discovery of some scientific truth by some scientist, as in medicine, physics, electricity and mechanics.

Geological papers were presented by Dr. Charles R. Keyes on 'Depositional Equivalent of Hiatus at Base of our Coal Measures'; and the 'Arkansan Series,' a new terrane of the carboniferous in the western interior basin. The present Arkansas valley, however, has probably been formed entirely since Tertiary times, and by a system of drainage in no way dependent upon the carboniferous drainage. Where the great uplift of Missouri and Arkansas over the northern part—embraced by the so-called Ozark isle—and the southern part composing the Ouchita mountains were made up of resistant limestones, these yielded less quickly to erosion than the central soft shales; and the Arkansas river, which happened in old peneplain to traverse the central part of the uplifted area, was able to cut its way down as fast as the region rose, and was thus able to maintain its old course. In his paper on 'Names of Coals West of the Mississippi River' he indicated the stratigraphical units of the carboniferous in the western interior coal fields—the terranes of the Missourian, Des Moines and Arkansan being given. In a paper on the volcanic necks of Piatigorsk, Southern Russia, he briefly described the highest peak in Europe, Mt. Elburz, which is 18,526 feet above the level of the sea. Mr. T. E. Savage briefly gave an account of the 'pre-Kansan Drift Exposure in Tama County, Iowa.' His conclusions were based on the buried soil, in which organic matter was found, leaching, and an oxidized zone. Professor Shimek made a comparison of the loess and modern 'Molluscan Fauna of Iowa City and Vicinity.' A large number of the species enumerated are aquatic.

Of chemical papers, Professor Nicholas Knight, on 'Some Recent Analyses of Iowa Building Stones,' stated that the chemical composition varied from nearly typical dolomite to admixtures in different proportions of calcium carbonate and dolomite. In his paper on 'Potable Waters' chemical an-

alyses were recorded for deep wells in Mount Vernon as well as analyses from the Cedar river. The wells were all more than 100 feet deep, the albuminoid ammonia running as high as .088, free ammonia .084, nitrates 1.38; the latter amount of nitrates was found in an artesian well which supplies the city of Mount Vernon and is 330 feet deep.

Dr. J. B. Weems and Mr. J. C. Brown presented a paper on 'The Influence of Chlorin as Chlorid in the Determination of Oxygen consumed in Water Analysis.' In this paper attention was called to the large amount of chlorin as chlorids in the deep well waters of the State. Naturally in the determination of the oxygen consumed in these waters there is a question of interest as to the effect of the chlorids in the potassium permanganate solution. The effect of chlorin in the form of sodium chlorid, in amounts from 5 parts to 1,800 parts per million of water, was investigated, using the Kubel, Schultz, Tidy or English, and the Association methods.

Another paper by the same authors considered the chemical investigation of a well which was the probable cause of an epidemic of typhoid fever.

Dr. J. B. Weems and Mr. H. N. Grettenberg presented a paper on 'A Study of Some Cotton-seed Oils' in which the analytical results of nine samples of cotton-seed oils were given and the results compared with the usual standards for oils of this class. Professor Alfred N. Cook discussed the 'Diphenyl Ether Derivatives,' being a summary of our present knowledge of the subject, as well as some original work on the diphenyl ether derivatives.

Zoological papers were presented as follows: Professor H. M. Kelly, 'Notes on the Time of Sexual Maturity in Certain Unios.' He believes that the period of sexual maturity does not always recur every year. Professor H. W. Norris in a paper on a 'Combination of Chromic Acid, Acetic Acid and Formalin as a Fixative for Animal Tissue,' gave excellent results for fixing mammalian tissues—in some tissues better results than he has been able to obtain with any other fixing fluid; it is especially good for glands and mucous epithelium. It is not satisfactory for nervous tissue. In his paper on the 'Morphology and Function of the Amphibian Ear,' Professor Norris stated that in this transition class of vertebrates, the Amphibia, the organ of hearing originated from an organ of equilibration which latter function is always retained. Professor H. E. Summers presented a paper on the 'Generic Synopsis of the Nearctic Scutelleridæ and Cydnidæ.' Professor E. D. Ball presented a monograph on 'A Review of the Tettigonidæ of North America North of Mexico.' Of the 500 or more described species the great majority are found in the region between Mexico and Brazil. Seven genera are represented in America north of Mexico.

Bacteriological papers were presented as follows: C. H. Eckles, 'A Comparison of Media for the Quantitative Estimation of Bacteria.' It was noted that ordinary peptone agar is not suitable for the development of a large number of bacteria, especially the lactic acid species. Both lactose gelatine and lactose agar gave much better results than either peptone agar or peptone gelatine. L. Russell Walker, in a paper on 'Sewage Disposal,' with special reference to the number of bacteria found in the sewage and effluent of the Iowa State College sewage plant from September 1, 1899, to September 1, 1900, stated that it was found that the percentage of gas-producing bacteria was greatest in the manhole and least in the effluent, while the number in the tank lies between. L. H. Pammel, in 'Notes on the Bacteriological Analysis of Water,' gave the results of an examination of the water supply of the Iowa State Col-

lege as well as other wells in the vicinity of Ames, and especially the wells that were supposed to have conveyed typhoid fever to the students of the college. There was shown to be a very wide variation, but in the case of the epidemic at Ames the milk was shown to have been the agent that conveyed the disease.

Botanical papers were presented by H. A. Mueller on the 'Shrubs and Trees of Madison County'; T. J. Fitzpatrick, on the '*Cupuliferæ* and *Juglandaceæ* of Iowa,' and one by F. M. Witter, on 'Some Observations on the Flora of Southern Alabama and Louisiana.' James E. Gow presented a 'Preliminary List of the Flowering Plants of Adair County.' Mr. F. W. Faurot described the early development of *Astragalus caryocarpus*. In fixing, best results were obtained by the use of Flemming's, although platinic chloride also gave good results. Professor Shimek, in his paper, 'Addenda of the Flora of Lyons County,' reported *Juglans nigra* and several herbaceous plants for that county. L. H. Pammel presented a paper on the 'Thistles of Iowa.'

An expedient for maintaining a constant temperature through the process of salt-glazing clay was presented by Ira J. Williams.

A committee on pure food legislation, consisting of C. O. Bates, J. B. Weems, Nicholas Knight, M. Ricker and W. S. Hendrixson was appointed, and also one on forestry, consisting of L. H. Pammel, T. H. Macbride and H. A. Mueller.

L. H. PAMMEL.

THE NEBRASKA ORNITHOLOGISTS' UNION.

THE annual meeting of the Nebraska Ornithologists' Union was held in the lecture room of the Omaha City library, January 12, 1901. President J. S. Trostler called the meeting to order for a business session which occupied the morning. During the noon hour the visiting members were the guests of the resident members, who had a luncheon prepared in the dining-room of the Omaha Commercial Club. The afternoon was devoted to the reading and discussion of papers. Measures were adopted and resolutions drafted in the interest of greater protection for all birds of the State. It was the expression of the body that the growing revulsion of feeling against bird slaughter would soon lead to such improved sentiment that the hunter's path through the woods could not be tracked by the blood of birds shot indiscriminately.

In the absence of Mr. J. H. Ager, State Warden of the League of American Sportsmen, Professor Lawrence Bruner reported upon an important measure for the protection of fish, game, and birds, to be presented for legislative action at the present session. The recent balloting for officers resulted as follows: *President,* Erwin Hinckley Barbour, Lincoln; *Vice-President,* Miss Elizabeth Van Sant, Omaha; *Corresponding Secretary,* J. C. Crawford, Jr., West Point; *Recording Secretary,* Robert H. Wolcott, Lincoln; *Treasurer,* Charles Fordyce, University Place; *Executive Committee,* Lawrence Bruner, Lincoln; F. H. Shoemaker and J. S. Trostler, Omaha. The Secretary announced the present membership as ninety-five.

PROGRAM.

President's Address, 'History of Ornithology in Nebraska and of State Ornithological Societies in General,' by J. S. Trostler, Omaha.

'The Relation of Birds to Agriculture,' by L. Bruner, Lincoln.

'Injurious Traits of the Blue Jay,' by E. D. Howe, Table Rock.

*'Ornithology in the Schools,' by Wilson Tout, Utica.

'The Value of Birds as Objects of Study in the Grades,' by Chas. Fordyce, University Place.

'A Late Nest of the Ruby-throated Hummingbird,' by Frank H. Shoemaker, Omaha.

'Young Rose-breasted Grosbeaks, by Elizabeth Van Sant, Omaha.

'The Breeding of the Prothonotary Warbler in the

* Read by title.

Missouri River Bottom,' by M. A. Carriker, Nebraska City.

'Observations on Traill's Flycatcher,' by M. A. Carriker, Nebraska City.

* 'On the Distribution and Breeding Habits of Bell's Vireo,' by Merritt Cary, Neligh.

'Some Notes on a Chimney Swift Tree,' by J. S. Trostler, Omaha.

'Birds that Nest in the State,' by L. Bruner, Lincoln.

'A Peculiar Disease of Birds' Feet Observed in Western Nebraska,' by E. H. Barbour, Lincoln.

* 'Intestinal Parasites of Nebraska Birds,' by H. B. Ward, Lincoln.

* 'Changes in the Bird Fauna of the Prairies in the Last Thirty Years,' by L. Sessions, Norfolk.

'Additional Observations on the Birds of Northwest Nebraska,' by J. M. Bates, Long Pine.

'Results of a Collecting Trip to Sioux County,' by J. C. Crawford, Jr., West Point.

'Notes on Cherry County Birds,' by J. S. Hunter, Lincoln.

'Notes on Birds from Western Nebraska,' by A. R. Graves, Kearney.

'Notes on Some of the Rarer Birds of Gage County,' by M. H. Swenk, Beatrice.

'Additional Observations on the Keeping of Records,' by R. H. Wolcott, Lincoln.

'Sketch of M. L. Eaton,' by R. H. Wolcott, Lincoln.

* 'Behavior of Birds when driven from their Nests,' by W. Edgar Taylor.

'Miscellaneous Notes.'

After President Trostler had inducted the newly elected President into office, the meeting was adjourned.

EDWIN H. BARBOUR,
UNIVERSITY OF NEBRASKA. *Secretary.*

THE KANSAS ACADEMY OF SCIENCE.

THE thirty-third annual meeting of this Academy was held at Topeka on Dec. 28–29. The following papers were read:

E. B. Knerr reported upon an artesian well at Muskotah, from which a very potable water flows at the rate of fifty-five gallons per minute. This water has a temperature of 56° F. J. T. Willard gave an account of some experiments on the relative digestibility of raw and cooked proteids. The experiments were made upon peas, beans, oatmeal, and flour, with a weak pepsin solution. The general results showed that the proteids in all these articles were much more digestible raw than cooked. While cooking diminishes the digestibility of the proteids, it of course increases that of the carbohydrates. The same author reported some results obtained at the Experiment Station in reference to the effect on the soil of continuous cropping of wheat. The figures given showed that the soil was in a marked degree deprived of soluble phosphoric acid by this continuous cropping. Parallel analyses were made of the soil of a field where wheat had been grown continuously for many years, and of an adjoining field where a variety of crops had been grown, and in the latter this loss of phosphoric acid did not occur. Professor Willard also discussed the effect of oxygen upon organic life. The tests made showed that, as far as the lower animals were concerned, it made very little difference whether they breathed oxygen or ordinary air.

A. E. Langworthy gave a complete report of a diamond drill boring recently made at Atchison. The drill disclosed no less then sixteen seams of coal, having together a thickness of fourteen feet and six inches. The most interesting of these seams are a 36-inch seam at a depth of 1,123 feet, a 28-inch seam at 1,187 feet, and a 15-inch seam at 1,197 feet. The 36-inch vein is a specially good quality of coal. An analysis of the Mississippian limestone, from this boring, is reported by Fred. B. Porter. W. C. Bauer reported on the work of the United States Coast and Geodetic Survey as carried on at Baldwin.

C. N. Gould read a paper on the salt plains of Oklahoma. The largest of these covers an area of nearly 50 square miles. Salt springs are found in various localities, so that a practically inexhaustible supply of salt can be obtained. The same author reported on the 'Southern Extension of the

* Read by title.

Marion and Wellington Formations' and on 'The Dakota Cretaceous of Kansas and Nebraska.' A. S. Hitchcock gave a list of the plants collected in Lee County and other localities in Florida, a region of great interest to the botanist on account of the diversity of the flora.

Warren Knaus, in reporting on the additions to Kansas coleoptera, stated that the number of known species is now 2,500. W. K. Palmer gave an illustrated paper on 'The Value of Geographical Methods in the Teaching of Thermodynamics'; also on 'The use of Ball-bearings for General Machinery and on Principles of Chimney Design.' E. C. Franklin discussed the experiments that he has been conducting during the past year, upon the use of 'Liquid Ammonia as a Solvent.' Many of these experiments, which have already been published, throw a great deal of light upon the new theories of solution. An interesting paper on the Americus limestone, was presented by Alva J. Smith. The area covered by this excellent building stone was discussed, and an analysis given. L. E. Sayre spoke on the 'Medicinal Plants of Kansas.' He mentioned the medicinally valuable plants of the Asclepiadaciae and gave the geographical distribution of the medicinal plants of this genus and the commercial value of the products.

J. R. Mead gave an interesting paper on the peculiar formation known as the 'Flint Hills'; and also one upon the 'Archeology of Catalina Island,' illustrating the latter paper with fragments of ancient vessels. S. W. Williston described a new cretaceous turtle which he has recently studied. A paper from Edward Bartow gave an account of the work being carried on at the Laboratory of the State University on 'Sanitary Water Analysis of the Kaw River' and other streams and miscellaneous sources of supply in the State. Grace B. Meeker read a paper that attracted much interest, upon the wild flowers of the locality that are adapted to cultivation. This brought out a discussion in which much valuable information was elicited. J. W. Beede reported on 'Some Contributions toward a Monograph of the Permian of the central United States' and also, in connection with C. N. Gould on 'The Kansas-Oklahoma Triassic and its Invertebrate Fauna.' The same author discussed the 'Atchison Shales.' E. H. S. Bailey gave the analysis of a Mangano-ferrous mineral water, that contains more manganese than any water that has been previously noticed. L. N. Morscher read a paper on 'The Rôle of Isostacy.'

H. P. Cady has devised a new method for the detection of arsenic, antimony and tin. The arsenic is precipitated in a concentrated hydrochloric acid solution by a current of hydrogen sulfid gas, and to the solution hydrogen sulfid water is carefully added, when the antimony will be precipitated, and upon the further addition of the same reagent tin will be precipitated, so that at the end of the operation there will appear three distinct layers of sulfids of the metals in the test tube. Geo. H. Curtis read a paper on 'The Food of Fishes in central Kansas.' J. C. Cooper reported on some interesting specimens of nodular pyrites.

Several valuable lists were placed on record, as that of 'The Spring Flora of Cowley Co.,' by Mark White; a catalogue of the 'Goss Ornithological Collection' by B. B. Smyth; a list of 'Birds observed in Dickinson County' by D. E. Lanz; a catalogue of the 'Crayfishes of Kansas' by J. A. Harris.

The evening of Friday was occupied by the address of the retiring president, A. S Hitchcock, on 'Ecology, or the Effect of Environment upon Plants,' an illustrated lecture on 'The Milky Way,' by E. Miller, and another paper, also illustrated, on 'Mines and Minerals of Kansas,' by G. P. Grimsley.

E. H. S. BAILEY.

*THE STANLEY-McCORMICK HOPI EXPEDITIONS.**

IN 1897 the Hopi collections of the Field Columbian Museum were comprised within three cases and consisted chiefly of a gift from Mr. Ayer, supplemented by a small collection purchased from Mr. Keam, a Hopi trader. During this year I made an extended collecting trip through a number of the Western States, visiting on my return the Hopi pueblos, where I remained five days, which were spent in collecting ethnological material. From several sources, previous to my visit, I had heard of a collection which the missionary Mr. H. R. Voth had been forming during a number of years, to assist him in his studies. While examining this collection I was at once impressed not only with its great beauty and richness, but with the detailed knowledge which Mr. Voth possessed concerning every object in his collection. At that time there was no willingness on his part to sell any or even a portion of the collection, and in fact its sale was not even seriously considered.

In December, 1897, I revisited Oraibi, the largest of the Hopi villages, in company with Mr. Melville, an attaché of the department as modeler and sculptor. The object of this visit was to secure life casts of several Hopi for the production of a large group which would illustrate certain phases of their house life. Mr. Voth had in the meantime enlarged his collection, and I was more than ever brought to a realization of the value of its accession for our Museum. I returned to Chicago with the idea that we should secure the Voth collection, as well as the services of Mr. Voth that he might arrange the collection and construct certain altars, etc., illustrative of the religious life of the Hopi.

Shortly after my return I consulted with Mr. Ayer in regard to the matter, and it was through his interest in the Museum that the subject was brought to the attention of Mr. Stanley McCormick, who, in January, 1899, notified me that he would contribute a certain sum toward the work, as had been outlined by me. Within a few days after this announcement of McCormick's intention, Mr. Voth arrived at the museum and began work, continuing with the museum uninterruptedly until May 1, 1900, when he left for Oraibi again to assume his duties as missionary. During Mr. Voth's connection with the museum his entire collection was installed, nine altars, involving an immense amount of detailed labor, were constructed, and over 1,700 labels were written. While Mr. Voth had never had previous experience in museum work, his natural ability was so great, his knowledge of the subject so profound and his earnestness so intense, that a great deal of work was accomplished in that time, and it was with no little degree of regret that I saw Mr. Voth leave for his field of work as missionary.

While the collection acquired from Mr. Voth contained a large amount of ancient pottery, yet the major part of the collection was purely ethnological, and it soon became evident that if we were to derive full benefit from the opportunities which presented themselves in Arizona for a complete exhibit of a single tribe, we must at once set about to secure a proper representation of ancient Hopi life, as remained concealed within the ancient house ruins and burial places. Much archeological investigation of this sort had already been carried on by other investigators, especially by Dr. Fewkes of Washington, who for many years had devoted much time to this work and always with consummate success. I decided, therefore, that while attempting to make our collection representative of all parts of the territory covered by the ancient Hopi, we should pay especial attention

* Read before the Chicago Society of the Archeological Institute of America, December 18, 1900.

to the ruins which heretofore had been lightly passed over; especially was it my desire that we might discover new ruins where yet remained interesting material. In accordance with this idea Mr. Burt, an assistant in the department, left Chicago early in December of 1899, and began a series of explorations in the well-known ruins of Homolobi near Winslow, on the Little Colorado River. He pushed on to the west, following the course of the river, and investigating one ruin after another for a distance of seventy-five miles. The result of this expedition was that our knowledge of the Hopi was considerably extended in a hitherto unexplored region, which was occupied by several clans, where the manufacture of the so-called yellow ware of the Hopi had not been practised. In none of the ruins explored by Mr. Burt beyond the point known as Cable Crossing, did he encounter any of this so-called yellow ware, but large quantities of other ware, the black and white predominating. About the same time that Mr. Burt left for the Little Colorado, Mr. Voth and I left Chicago for Oraibi, where we spent a little less than a month. The object of this—the second McCormick expedition—was not so much to secure material as to get additional information regarding certain altars. In this we were entirely successful, and while there had the good fortune to witness the nine day Soyal or Winter Solstice ceremony. Full notes were taken on this interesting ceremony and it will form the subject of a Museum publication shortly forthcoming. A number of interesting objects were also added to the collection on this expedition, of special interest being a number of masks and certain *tihus* or dolls which had never before been reproduced for the purpose of trade. Early in the present year, Mr. McCormick's attention was called to the fact that additional funds would be needed if the work was to be carried on, and he very generously announced his intention of making provision for the continuation of the work and above all for an extension of archeological investigations among the ruins.

Early in May of this year I again sent Mr. Burt, on the third McCormick expedition, to the Lower Colorado, in order that the work which had been abandoned on the previous year, on account of the setting in of winter, might be continued. Mr. Burt continued his explorations on into the country of the lower Little Colorado river, reaching on this occasion Black Falls. As a result of this expedition many additional specimens, including a large number of turquois beads, implements, utensils and ornaments of stone, bone and shell were secured, as well as a number of skeletons which will prove of the greatest value when the time comes to attempt to reconstruct the past life of the Hopi, so far as relates to their physical characteristics. It is only just to Mr. McCormick to say that he very generously made special provision for this second expedition of Mr. Burt's. The fourth and last McCormick expedition has just terminated after a period of eight months; this was in charge of Mr. C. L. Owen, also an assistant in the department, who left Chicago early in May. Mr. Owen confined his attention to the ruins located within the limits of the so-called Province of Tusayan, and the first five months of his time were spent in excavating at the great ruins of Sikyatki, Awatowi, old Mishonovi and old Cunopavi. All these ruins were well-known to scientists, and from many of them collections of considerable importance had been made, but so valuable are they for the purpose of reconstruction of the past history of the Hopi that it was considered especially desirable to form as large a collection as possible from each one. In this Mr. Owen was entirely successful, finding a hitherto unknown burying ground at

Sikyatki which yielded important results, and from Mishonovi—one of the most important of the Hopi ruins—securing over 600 pieces of decorated pottery alone, while from other regions he secured representative collections. Having exhausted the region in the immediate vicinity of the present Hopi villages he turned his attention to ruins of the North, many of which had never been previously visited by any scientist. While in this region he discovered ruins which we have reason to believe had never been seen by any white man. As a result of this expedition the Museum acquired nearly three thousand invaluable specimens, comprising every object which we might reasonably expect to find in graves or house ruins, and including a large number of rare forms of bahos or prayer offerings. Many unusual forms of stone implements, idols, and mask forms were found, while especially noteworthy are four painted stone slabs which probably once served in some Hopi altar and of which specimens have rarely ever before been found. Concerning the exact value of the contributions which may be made to science as a result of this last Hopi expedition it is of course too early yet to speak, but that our knowledge of the Hopi and of their migrations has been extended in many ways there is no question.

Finally there may be considered the contents of the two halls in the Field Columbian Museum devoted to the Hopi, for here, it may be properly assumed, are the visible, tangible results of these McCormick expeditions. Of the thirty-four cases which contain these collections, eleven are devoted to the ordinary every-day life of the Hopi. Here we may trace in detail, by means of thoroughly labeled specimens, models and three life-like groups, the domestic life of the Hopi through every phase of industry—such as pottery-making, basketry, spinning and weaving, costumes, stone and bone utensils of various sort, etc. In the same room with these domestic collections are to be found several cases containing such of the material from ancient ruins as has been put on exhibition. These collections, however, it is to be expected, will be removed from this hall and shown in an adjoining hall along with collections which have been derived from the last two expeditions and which may be derived from further expeditions.

Much might be said of the interest attaching to the numerous specimens which these expeditions have yielded, but attention can only be directed to a single group of objects, namely, the yellow ware food bowls. Each one of these bowls is beautifully made (in fact no finer pottery has been found in America) and they are generally decorated on the interior with certain mythological figures or symbols. Among these bowls are very few duplicates, each one having its own story, having served during the life of its owner its own peculiar mission.

The second Hopi room is devoted to ceremonies and to the religious life in general of the Hopi. In this hall no distinct phase of the ceremonial or religious life has been omitted, and simply to show the fullness and richness of the collection, mention may be made of two or three categories of objects. While the Hopi are not greatly addicted to smoking, yet the use of tobacco forms a very important part in all of their ceremonies, and, for the production of smoke which shall symbolize clouds, special forms of pipes are used, known as cloud blowers. In other ways also during ceremonies pipes of special construction or design are used. The collection numbers over sixty interesting and carefully labeled specimens of pipes, many of which are extremely rare forms. During the ceremonies many forms of bahos or prayer messengers are used, and as these bahos are not made

for the purpose of trade, but as a rule are immediately after consecration deposited in shrines or springs, they are rather difficult to obtain, yet the collection numbers over 150 specimens of these interesting objects, representing nearly every form of baho known to the Hopi.

The figurines produced by the Hopi men and given by the mothers to the children during the *Niman*, or Farwell ceremony, and known as *tihus*, are objects found in all Hopi collections, but as a matter of fact these *tihus*, which represent certain mythological personages called *Katcinas*, are only reproduced for a limited number of characters. Owing to the unusual zeal shown by Mr. Voth toward the collection of this class of objects, the collection, with the recent addition of specimens brought home by Mr. Owen, numbers not less than 275, comprising over two hundred distinct varieties, a great many of which were reproduced for Mr. Voth only after earnest endeavor on his part. Inasmuch as these *tihus* represent *Katcinas* and as these *Katcinas* play a very important part in the religious life of the Hopi the importance of a collection of this magnitude, carefully arranged and labelled, can not be overestimated. Even more difficult than these *tihus* to obtain are the masks which are worn by the Hopi as they personate deities in the *Katcina* dances. The Hopi regard these masks with considerable reverence and do not willingly part with them, yet the collection numbers one hundred and thirty specimens, many of them being made of elk or buffalo hide.

But more important than these collections, however valuable and interesting, are the altars and sand mosaics, which are faithful, painstaking reproductions of altars which are erected year after year in the underground *kivas* of the Hopi. There may come a time when the actual altars themselves may be obtained, but up to the present, so highly are they revered by the Hopi that no sum of money, however great, would induce them to part with a single slab from a single altar. The altars reproduced by Mr. Voth number nine, namely—the Antelope, Snake, Flute, Powamu, Powalawu, Katcina, Soyal, Marau and Oöquol. These altars are such as are erected by the Hopi during the great nine-day ceremonies, and while they do not exhaust the subject for even a single Hopi village, they are by far the most important altars and comprise within their number all those which contain images or fetishes. In most of the ceremonies represented by these altars, during the years when initiations are performed, sand mosaics are added to the altar, and comprised within the altars which have been reproduced are all those which contain this additional feature of interest. Mr. Voth also reproduced the great Ballülukon screen which is erected in the *kiva* during one of the ceremonies, and which is manipulated by means of concealed wires, to the intense delight of priests and the great mystification of the novitiates present.

The work which has been accomplished by the McCormick expeditions up to the present time has, I believe, been thorough and in every sense worthy the generosity of the patron. It must be admitted, however, that much yet remains to be done of equal value and importance among the Hopi of to-day and among the ruins of the past.

Field Columbian Museum.

SCIENTIFIC BOOKS.

An Atlas of Representative Stellar Spectra from λ 4870 to λ 3300, together with a Discussion of the Evolutional Order of the Stars, and the Interpretation of their Spectra, preceded by a Short History of the Observatory and its Work. By Sir William Huggins and Lady Huggins. London, William Wesley & Son.

This sumptuous volume of 165 folio pages worthily represents a part of the work which has been quietly in progress during the past forty years at the little private observatory at Upper Tulse Hill, London, one of the most important outposts at the frontier of astrophysical science. The additional title, 'Publications of Sir William Huggins's Observatory, Vol. I.,' leads us to hope that this introductory volume may soon be followed by others which shall give in similar manner the results which have been gained from the minute study of the large store of photographs which have been secured by the talented authors during many years of patient experiment and observation.

The first chapter gives a brief 'history of the observatory, and of the work done therein.' At the present day, when a photograph of the spectrum of a bright star may be obtained with an exposure of but a few minutes,—or even seconds, we are likely to fail to appreciate the difficulties and discouragements of the pioneers in these delicate researches, and we may forget how our present large and rigid instruments have slowly evolved from the first combinations of spectroscopes and telescopes. It was soon after the establishment of the private observatory that Mr. Huggins learned of the discovery by Kirchhoff and Bunsen of the true nature of the dark lines of the solar spectrum, which had been unexplained for more than half a century after their discovery. It at once suggested a wide field of research, and, as the author states, 'then it was that an astronomical observatory began, for the first time, to take on the appearance of a physical laboratory.' With the collaboration of Professor W. A. Miller, the spectra of forty stars and of Jupiter and Mars had been observed at the end of 1862. The news of the similar work of Mr. W. M. Rutherfurd in America arrived on the day the preliminary paper was to be read at the Royal Society.

The photography of stellar spectra was attempted in 1863, the wet process, of course, being employed, but the dark lines were not shown on the plates until the attempt was resumed in 1875. Meanwhile the chemical origin of a number of the lines in stellar spectra was established, and in 1864 Mr. Huggins made his famous observation on the spectrum of a nebula, demonstrating its gaseous constitution. In 1866 a temporary star, *Nova Coronæ*, was first observed spectroscopically; and in the same year was begun the construction of a spectroscope for determining the velocity of stars in the line of sight, the results of the use of which were published in the *Philosophical Transactions* in 1868. Later, attention was given to the spectra of comets, and to attempts at the spectroscopic observation of the red prominences previously only seen during solar eclipses. Although the principle underlying their visibility in the spectroscope was clearly stated by Mr. Huggins early in 1868, he did not actually succeed in detecting them until after their discovery by Lockyer and Janssen later in that year.

Larger instruments and the dry-plate process permitted much progress in the work on stellar spectra after 1875, which is recorded in numerous papers read before the Royal Society in the subsequent years. The titles of eighty-two papers on work done at the observatory are given in the second chapter of the work. Chapters III. to V. describe the instruments and methods of obtaining the spectra, and of broadening them, the descriptions being largely quoted from the journals in which they were originally printed.

Chapter VI. occupies one quarter of the volume, and is entitled 'Discussion of the Evolutional Order of the Stars and the Interpretation of their Spectra,' with sections on (1) the types of stellar spectra, (2) original differences of stellar constitution, (3) classification of stellar spectra, and (4) physical and chemical interpretation of stellar spectra by means of terrestrial spectra observed in the laboratory.

In addition to its absorbing interest to students of astronomy, this chapter can hardly fail to be attractive to the general reader of scientific topics. The author quotes freely from his published addresses bearing upon this subject, and brings into discussion the work of other astronomers and physicists, although drawing his observational data chiefly from his own work. In the matter of classification of stellar spectra the author follows in the main the scheme suggested by H. C. Vogel in 1874.

The white stars are considered to be in a more diffuse state than our Sun, and hence in an earlier stage of development. The subdivision represented by Bellatrix, which has a characteristic spectrum of the 'Orion type,' is placed first in the order of stellar evolution. Considerable space is devoted to the question of which class of spectrum corresponds to the highest temperature of the radiating photosphere, and numerous lines of evidence are adduced to support the view that this is found in case of the stars with spectra of the solar type. The argument based upon the relative extension of the continuous spectrum into the ultraviolet region, the extension of the solar type being regarded by the authors as the greatest, is not wholly convincing, as the difficulty of securing identical conditions of exposure, atmospheric absorption, etc., in the case of different stars of different types, is very great. But emphasis is well placed upon the importance of taking into account more fully than has hitherto been done the large diminution in the star's effective radiation from the integrated effect of the selective absorption of its atmosphere; that is, from the absorption represented by the very numerous dark lines in spectra of the solar type.

Attention is drawn to the important effect of the convection currents in stellar atmospheres, and their increasing activity in the region where the dark lines originate, as the stars advance in age. This increase is assigned as a possible cause of the diminished prominence of the hydrogen lines in the spectra of the second and later types.

The reasons for the presence of certain particular lines of certain particular elements in the spectra of stars at different stages are considered by the authors to lie in the conditions of the absorbing region, as to density and composition, particularly the mixing of various vapors. The absence of the metallic lines from the spectra of the first type is attributed in part to the slight convectional effects in the very diffuse atmospheres of these stars, so that as a result of diffusion hydrogen and the lighter elements preponderate in the region where absorption occurs; and in part to a slow temperature gradient, so that the vapors just above the photosphere might differ in temperature too little from the photosphere for their lines to be seen as dark on the continuous spectrum.

The effect of density of the vapor is quite fully considered, particularly in connection with the laboratory experiments of the authors on the behavior of the calcium lines.

The twelve half-tone plates which illustrate the volume are admirably done, and represent extended and skilful work by the authors in their arrangement. Plate II. contains reproductions of numerous 'historical spectra,' as they are well named, obtained by the authors between 1876 and 1895. These are fully described in Chapter VII. The remaining plates receive a 'preliminary discussion' in Chapter VIII.

The treatment of the subject as a whole is qualitative rather than quantitative, and is not mathematical, so that the general reader can follow the clear and philosophical reasoning of the authors without the necessity of a previous familiarity with technical symbols.

Artistic head pieces and initials appropriate to the subject, the hand work of Lady Huggins, complete the adornment of the volume. The work has received the Actonian prize of the Royal Society, and the election of Sir William Huggins to the presidency of the Royal Society at this time will be recognized as highly appropriate.

EDWIN B. FROST.

Annual Report of the Chief of the Bureau of Steam Engineering of the U. S. Navy Department, 1900. Washington, Government Printing Office. 1900. 8vo. Pp. 128, pl. 17, folded.

This report, apart from its importance as detailing the work in applied science of one of the most important bureaus of the U. S. Government, has a peculiar interest at the moment to all who have become aware of the tendency illustrated, for example, in the operation of the National Observatory and of the Coast Survey, toward amateurism in all branches of the Government service. The Engineer-in-Chief of the Navy, Admiral Melville, is one of the most competent expert professionals in the Navy, or outside it, in his department, and his report, while giving an admirably condensed account

of the operations of his bureau during the official year 1899–1900, exhibits a state of affairs, in a vitally important department of public service, which must intensely interest, and at the same time alarm, every patriotic citizen.

The report includes a statement of the appropriations, and, in detail, the expenditures, of the branch of that departmental organization which is entrusted with the employment of two and a half to three millions of dollars annually in the design, construction, repair and maintenance of the naval machinery of our whole fleet. It gives an outline of the work in hand and an account of that performed during the past fiscal year, details of the inspection of contract work, and of the conduct and results of trial trips of new vessels in the Navy and of old craft repaired. It considers the character, numbers and efficiency of the personnel of the engineer department of the Bureau and of the fleet, the effect of recent and of proposed changes, and especially of such as affect the organization of the Navy Department and the crews of our vessels.

This Bureau has expended in the year reported upon over $2,500,000, of which about one-half represents costs of labor and one-half expenditures for materials. In addition to extensive work in the designing of new machinery, the Bureau is compelled to examine and report upon several thousands of detail drawings submitted by contractors. Some conception of the extent and importance of this work may be obtained when it is known that, for a single ship, the *Kearsarge*, about 600 drawings were made of approved constructions and an uncounted number of proposed variations or expanded details. Even small craft, like the torpedo-boats, require almost as much work, though on a smaller scale, as they have nearly as many working parts as the largest vessels. There are seventy vessels under construction, or about to be contracted for. For all this work, and for the operations of the fleet, large numbers of engineer and constructing experts are needed; but, meanwhile, the number available, which has for years past been entirely inadequate, is constantly being reduced by retirement, death and resignation; no proper arrangements having been made for its maintenance.

Where, for example, about twenty-five inspectors are needed, fifteen are to-day compelled to do the work as best they can, with evident risk to the efficiency of the service; where about thirty officers are needed at the Navy yards and stations, fourteen carry the burden, with similar risks to the service. 'The present force of engineer-officers is everywhere overtaxed,' but there is no way provided by which to relieve these officers or to add to their numbers, in a proper manner, the needed additional expert and experienced officers, possessed, as they should be, of an ample scientific and technical training and varied earlier experience. The ideal preparation is obviously some such preliminary general and special scientific education as is now, as a matter of course, presupposed in civil life, a professional apprenticeship and later experience in actual work of design and construction, and opportunities to exhibit that capacity for scientific work and for the management of productive organizations which, only, insures professional success, alike, in public and in private business. In fact, the tendency seems to be, in this as in so many other branches of the public service, to permit the most important affairs to drift into the hands of incompetents or, at best, of amateurs, personally clever, often, but entirely unequal to the conduct of affairs demanding special education, special experience, and native talent properly cultivated and developed by the common and essential process of evolution under the unsparing system of selection which obtains in a career of any sort in everyday life.

The Chief of Bureau protests, for example, against a proposed consolidation of the long-established bureaus of the Navy Department, in which a branch of the work of the service, as mechanical engineering, naval construction or navigation, is entrusted to a body of experts in that branch, presided over by a selected expert-chief detailed from the list of most experienced, talented and distinguished officers in the service. This must result, as is pointed out very clearly and convincingly, in either the introduction, as a general supervising officer,

of one who is expert only in his own special field or of one who has no expert knowledge of any branch. In the first case, the outcome would be what is seen in so many other governmental departments already: the subordination of able and competent men to an official without the ability to direct and who is made an official superior over men, each in his own department, without superior. In the second alternative case, the Secretary of the Navy, usually a man without any expert knowledge of the technical work of the service, will have, interposed between himself and the men who are competent to advise him, each in his own province, an officer equally incompetent with the Secretary himself—with the added and fatal disadvantage of giving to the new incompetent, authority over men technically educated and fully competent.

The vital principle that every important business should be conducted by an expert in that business is, in this case, ignored. Either course would, in the opinion of those most competent to judge, insure inefficiency in the operation of the naval service, of that arm on which the nation most relies to defend its honor and its rights in conflict with a foreign foe. But the most dangerous of foes is the amateur, in the position of an expert, controlling an important branch of public service.

The 'Personnel Bill,' passed by Congress as an emergency measure during the excitement attending the outbreak of the war with Spain, and which consolidates the whole Naval Engineer Corps with the Line of the Navy, seems to have worked a mischief in a similar manner. Amateur talent is entrusted with duties and responsibilities which can only be safely assigned to experts of high scientific education, thorough professional training and ample experience. The members of the old Engineer Corps are dying off and the whole business of engineering is nominally becoming shifted into the hands of line-officers without other than amateur knowledge of the business, and with obvious danger to the whole naval service. Either the law is defective or it is not found practicable to secure its intended results; but, whichever may be the fact, the important outcome is danger of sacrifice of the vital interests of the Navy to amateur incompetence. Nor is there the excuse in lack of knowledge of the danger, in advance. Every report of the chiefs of bureau of earlier years, for a generation past, has included a warning, often earnest and impressive, of this coming danger; while, throughout the whole period, the steady reduction of the numbers of officers in this most vitally important of all divisions of the modern naval personnel has been progressing, and the dangerous change has been advancing toward a crisis, despite the constant warnings, not only of all chiefs of bureau, but of substantially all old members of the wrecked corps.

The constant danger to the Naval Observatory and its personnel through amateurism has been as constant a subject of protest, in the same manner and with no better result; but this introduction of amateurism into the seagoing navy is even more serious and is certain to result in more serious disaster.

R. H. Thurston.

A Record of the Geology of Texas for the Decade ending December 31, 1896. By Frederic W. Simonds, Ph.D., Professor of Geology in the University of Texas—Transactions Texas Academy of Science for 1899, Vol. 3, Austin, Texas, October, 1900.

This work is deserving of more than passing notice for Professor Simonds has not only given a most painstaking and complete bibliography of the geology of the Texas region, but as truly expressed in the title a record of the same. Each of the 466 works noted is accompanied by an intelligent abstract or synopsis, so that this book becomes of greatest value to any one wishing to ascertain information concerning the Texas region for the decade ending with the year 1896. The task of compiling such a work at Austin, so remote from good library facilities, must have been enormous, and is a credit to Professor Simonds, the Texas Academy of Science and the University of Texas.

It is gratifying also to note that this work is but one of the recent manifestations of the quickened and improved condition of the University of Texas. Within the past ten years this institution has been gradually acquiring a faculty of progressive and able men and has made

a steady growth in every department, which places it in the front rank of Southern institutions and equal, if not ahead, of many of the older colleges of the North. Under the administration of President Prather its work is steadily advancing and it is to be hoped that the Legislature of Texas will see the necessity of an enlarged and ample endowment.

ROBT. T. HILL.

BOOKS OF REFERENCE.

WE have received from Messrs. Lemcke & Buechner, New York, the tenth volume of the invaluable year-book of the learned world, 'Minerva,' which is now a volume of 1,235 pages. The frontispiece is an etching of Professor W. C. Röntgen, the other men of science selected for this purpose in previous volumes having been Pasteur, Kelvin, Schiaparelli and Nansen. The editor has been compelled to give up his plan of including in the work data of international congresses, which is regrettable, though the task of securing such information is doubtless difficult. As it is the work contains a vast mass of information—a rough calculation indicates that the names of about 32,000 scientific and learned men, connected with the world's institutions of learning, are included. The statistics of students given at the end show that the universities having an attendance of over a thousand students are distributed as follows: United States, 26; Germany and Austria, 24; Italy, 10; Great Britain and France, 8 each; Russia, 7; Spain, 4; Norway and Sweden, 3; Switzerland, Belgium and Canada, each 2; Denmark, Portugal, Egypt, Brazil, Chili, Philippines, New Zealand and Japan one each.

'WHO'S WHO' for 1901, published in London by the Blacks, and in New York by the Macmillans, is also a useful work of reference, giving as it does short biographies of the leading men and women of Great Britain and of a few Americans. All the leading British men of science are included, and it is interesting to note how many there are and what important work they have accomplished. It is impossible to discover by what principle or lack of principle the Americans have been selected. The provost of the University of Pennsylvania is there, but not the president of Harvard University. Mr. Tesla is included, but not the two or three of our most eminent men of science who have been looked up. The editing of the book appears to be careful, but not perfect. Thus to take a somewhat trivial example, Francis Darwin is said to be the son of 'Charles Robert Darwin,' George Howard Darwin is said to be the son of 'the late Charles Robert Darwin (author of the 'Origin of Species,' etc.)' and Leonard Darwin is said to be the son of 'the celebrated Charles Darwin, Down, Kent.' The 12,000 biographies, more or less, which the volume contains are certainly most useful for reference. In this connection it may be stated that a new edition of the American 'Who's Who' is in preparation, and the editor Mr. John W. Leonard, care of A. N. Marquis & Co., Chicago, will be glad to secure corrections and additions to the last edition.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Botanical Gazette* for January, 1901, contains a second contribution by Professor C. S. Sargent, 'On New or Little Known North American Trees.' This special fascicle of descriptions

includes a new honey locust from Texas and eight new species of *Crataegus*. Mr. Theo. Holm contributes an 'Anatomical Study of *Eriocaulon decangulare* L.,' from which he concludes that this genus and its allies are somewhat unique among the monocotyledons. Mr. B. M. Duggar, of Cornell University, records the results of 'Physiological Studies with reference to the Germination of certain Fungous Spores.' The number closes with the usual book reviews, notes for students and news items.

THE February number of *Popular Astronomy* contains an article by R. G. Aitken, of Lick Observatory, on the 'Orbit of Sagittarii,' accompanied by a plate of the orbit; the second part of Mr. How's article on the 'Best Astronomical Books for the Use of Students' takes up historical and biographical works in detail; J. F. Lanneau contributes notes on the eclipse, and Asaph Hall a note on 'Clairaut's theorie de la figure de la terre.' J. K. Rees, of Columbia Universitory Observatory, presents a full report of the observations on the November meteors during the years 1898, 1899 and 1900. An abstract is also given of the article by Kretz on the 'Star Coma Berenices' and a full account of the recent reports of the Board of Visitors of the Naval Observatory. An article by Professor W. W. Campbell shows how the observations of Eros will determine the sun's distance from the earth and a résumé of the scientific progress of the nineteenth century closes the general department of the number. In addition to the usual notes a new department is opened which gives news of 'Double-Stars, their Observations and Observers.'

SOCIETIES AND ACADEMIES.

SCIENCE CLUB OF THE UNIVERSITY OF WISCONSIN.

THE December meeting of the Science Club of the University of Wisconsin was addressed by Dr. C. R. Van Hise on the topic, 'The Earth's Story of the Ore Deposits.' This address, which was delivered to a large audience, treated in a briefer and simpler manner a subject which has recently been given an exhaustive treatment in addresses before the American Institute of Mining Engineers and the Western Society of Engineers, and which under the title, 'Some Principles controlling the Deposition of Ores' has been printed in the *Transactions* of the first-mentioned Society. The thoroughness of Professor Van Hise's investigations, which, starting on different lines, have converged upon a common point, set to rest many hitherto controverted questions and, from an application of newly determined principles in the fields of physical chemistry, applied mathematics and soil physics, as well as in geology, there has been evolved a theory of ore deposition which is both logical and in accord with observed facts. The theory may be said to be grounded on two important earlier investigations: one by Van Hise, showing that at the moderate depth of 20,000 meters all save the smallest cavities must close in even the hardest rocks, whereas in most rocks they must close at one-half that depth, and one on Slichter's elaborate investigation of the flow of underground waters, an investigation which has been considerably extended by Van Hise.

From the first-mentioned study it follows that the circulating waters, which it is almost universally admitted deposit the ores from solution, could not have come from below the depth of 20,000 (or perhaps 10,000) meters. The excessive friction of liquids moving in capillary tubes, and the consideration that probably 100,000 times as much liquid as ore must be transported seem to exclude the possibility of ascensional currents below this level, thus restricting their circulation to the thin outer shell of the earth's crust—*the zone of fracture.* This requires that the circulating water shall be of meteoric origin, and the fundamental premise is made that the motion of the waters is a result of gravitative stress.

Water flowing under head from one point to another through a homogeneous medium will utilize the entire cross-section (indefinitely extended), though the major portion will pass by the shortest route. If vertical fissure planes exist in the course of the liquid the lines of flow will be deflected so that above a certain point they will enter the fissure in a downward direction and below another point they will be di-

rected upward, while between the two points they enter laterally. It follows from this that a particular body of ore may have been formed by ascending, descending or laterally moving currents, or by any or all combined.

The level of ground water separates an outer *belt of weathering*—a belt in which oxidation, carbonation and hydration are producing soluble bodies—from an underlying *belt of cementation* in which deposition is continually taking place, often in connection with solution. In many mining regions the processes of degradation have removed several thousand meters of rock from above the present belt of weathering, but as the belt removed has all at some time been included within the belt of weathering, it is an adequate storehouse from which the ore bodies of the present belt of cementation have been supplied. Another fundamental premise is that materials will be more generally taken into solution during the descending course of waters and be deposited during the upward course toward the surface, both because the increasing pressure and temperature with increasing depth favor solution, and because the larger fissures near the surface—the trunk channels—allow the mingling of solutions. Since the same fissure may near the surface be receiving descending waters, a little lower down laterally moving currents, and at still greater depth ascending currents, it follows that as degradation brings successively lower and lower belts within the realm of action of ground waters, the first concentration of ores will, in general, be produced by ascending currents and the later concentrations (if there be any) by laterally moving or descending currents. The first concentration should be less in amount than later concentrations, a conclusion which is supported by observation, since nine mines out of ten are poorer below the 300 meter level than above it, and still poorer below the 600 meter level. Inasmuch as the deep water circulation is deficient in oxygen but contains reducing agents, while the shallow water circulation contains free oxygen, it is easy to explain the development of oxide ores in the belts near the surface. Dr. Van Hise holds that oxidized salts, such as sulphates, carried to greater depths, react upon the lean sulphides so as to precipitate the metals as sulphides from the solution. The above are only the broader generalizations in the earth's story of the ore deposits as read by Professor Van Hise.

WM. H. HOBBS.

THE TEXAS ACADEMY OF SCIENCE.

DURING the quarter ending December 31, 1900, there have been three noteworthy meetings of this organization. At the first, held in the Chemical Lecture Room of the University of Texas, Friday evening, October 26th, Dr. Simonds, the retiring President of the Academy, introduced his successor, Henry Winston Harper, M.D., F.C.S., who then delivered the Presidential Address, his subject being 'Some Advances in our Knowledge of Immunity and Protective Inoculation.' This address will be published in full in SCIENCE.

The second meeting of the quarter was held in the Chemical Lecture Room of the University, Friday evening, November 23, 1900. The program was as follows:

1. 'The Present Foundation of the Austin Dam,' by Professor T. U. Taylor, University of Texas.

2. 'An Application of the 57.3 Rule,' by Professor T. U. Taylor.

3. 'Eros and the Solar Parallax,' by Dr. Harry Y. Benedict, University of Texas.

The third and last meeting was held at Baylor University, Waco, Texas, December 28–29, 1900. The program was of unusual interest and covered a wide range.

1. 'The problem of Forest Management in Texas,' by Dr. William L. Bray, University of Texas.

2. 'Recent Progress in Insect Warfare' (by title), by Professor F. W. Malley, Agr. and Mech. College of Texas.

3. 'The Value of Coal Tar Products as Practical Wood Preservers,' by Instructor E. P. Schoch, University of Texas.

4. 'A Mathematical Problem,' by Professor J. B. Johnson, Baylor University.

5. 'The Cretaceous—the Kindergarten of Paleontology,' by John K. Prather, B.S., Waco.

6. 'The Silt Problem in connection with Irrigation Storage Reservoirs,' by Professor J. C. Nagle, Agr. and Mech. College of Texas.

7. 'The Need of Technical Education in the South,' by Dr. William T. Mather, University of Texas.

8. 'The Modern Presentation of Botany,' by Instructor A. M. Ferguson, University of Texas.

9. 'Note on the Occurrence of Mammoth Remains in McLennan County,' by Professor O. C. Charlton, Baylor University.

10. 'The Hydrographic Survey of Texas,' by Professor T. U. Taylor, University of Texas.

11. 'Theorem concerning Centers of Curvature of a Roulette' (by title), by Dr. M. B. Porter, Yale University, New Haven, Conn.

12. 'On the Floral Provinces and Vegetative Formations of the West Texas Region' (by title), by Dr. William L. Bray, University of Texas.

FREDERIC W. SIMONDS,
Secretary.
UNIVERSITY OF TEXAS.

ENGINEERING ASSOCIATION OF THE SOUTH.

THE regular monthly meeting of the Association was held on the evening of January 10th, at Vanderbilt University.

The death of Maj. Niles Meriwether, President of the Association was announced, and Messrs. J. S. Walker and Hunter McDonald were appointed a committee to prepare a memorial sketch of his life. The Association will feel most keenly this loss, for Maj. Meriwether has been a most active member.

A communication from Mr. J. C. Truatwine, Jr., Secretary of the 'Journal of Association of Engineering Societies,' was read. After some little discussion it was the unanimous opinion that the continuance of an individual publication was far preferable to uniting with the 'Journal of the Association of Engineering Societies,' and the Secretary was instructed to so notify Mr. Truatwine.

The first paper was a description of the methods of doing some bridge pier and foundation work in Chemulpo, Korea, by W. H. Holmes, an American engineer who has recently returned from that country. The system of keeping records of rivers in that ancient country was briefly described. They extended back into the past for many centuries and are said to be very accurate. Mr. Holmes stated that where an opportunity offered itself for a check the records were in every case sustained. The record for the river in question extended back 509 years and explanation was made at the beginning of the records that the history of the river previous to that time had been consumed in a fire which had burned the house and all contents.

The second paper was presented by Mr. Julian W. Kendrick, city engineer of Birmingham, Ala. It was an exhaustive study of the sewerage problem now confronting the Birmingham district. The geographical features of the drainage area were described, the difficulties in carrying out the various methods of sewerage set forth, and finally a plan proposed. The paper had been carefully prepared and was an interesting contribution on the sewerage question.

H. M. JONES,
Secretary.

VERMONT BOTANICAL CLUB.

AT the annual winter meeting of the Club on January 25th and 26th the following program was presented:

'The Finding of a Plumose Variety of *Asplenium ebeneum*,' by Mrs. Frances B. Horton.

'Some Common Confervæ,' by T. F. Hazen, Columbia University.

'Some Interesting Mosses Collected in Vermont in 1901,' by Dr. A. J. Grout, Boys' High School, Brooklyn.

'Are there Two Kinds of Hemlock in Vermont'? by Elroy C. Kent.

'Note on *Tremella mycetophila* Pk.,' by Dr. E. A. Burt, Middleburg College.

'Notes on the Last Season's Botanizing,' by Mrs. Nellie F. Flynn.

'Report of Progress on the Maple Sap Problem,' by A. B. Edson, University of Vermont.

'The Flora—What Next?' by Clifton D. Howe, University of Vermont.

'The Present Status of Vermont Botany,' by President Ezra Brainard, Middleburg College.

'A Botanical Trip to Joe's Pond,' by Mrs. Carrie E. Straw.

'Botanizing in the Bermudas,' by Dr. M. A. Howe, Columbia University.

'What Text-book of Botany shall be used in the High School?' by Miss Phoebe Towle.

'Wild Violets in the Garden,' by Miss E. Mabel Brownell.

'Are the Equisetums or Ferns Poisonous?' by Professor L. R. Jones, University of Vermont.

C. D. DIXLOWE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

A BIBLIOGRAPHIC CATCH TITLE FOR EVER AND EVER.

PROFESSOR MARK'S method of referring to bibliographic lists by name of author and number of year is worthy of general adoption; but it is not surprising that a difficulty should be

met with when an attempt is made to depart from the principle of the method by the introduction of an arbitrary symbol. Professor Mark (SCIENCE, January 4, 1901) proposes that the sixteen hundreds shall be denoted by 1600, etc., the seventeen hundreds by 1700, etc., the eighteen hundreds by '00, etc., and the nineteen hundreds by :00, etc. This method could be of value only if accepted universally, or at least by all scientific writers. The confusion introduced by inadvertently writing '23 for 1923 will be as great as if one had actually written 1823. But is it likely that this confusion will be avoided, seeing that many people already have dated letters and so forth '00 or '01, meaning 1900 and 1901? Setting this objection aside for the present, we note what difficulty Professor Mark has in finding a suitable symbol for the nineteen hundreds, and we wonder what is to be done with the next century, and with the one after that, and so on. If we are to settle this question in a scientific spirit, let us attempt something better than an apostrophe for 18, a colon for 19, a hyphen, say for 20, a dagger for 21, and such arbitary methods, all for the sake of saving an *em* space here and there or a few tenths of a second *per annum*. The irritation induced by the constant repetition of 18 or 19 is the least of the penalties we have to pay for the possession of ten fingers, and it is hardly enough to induce us to attempt yet once more some new method of notation. I therefore dismiss as impracticable all suggestions that familiar numerals should arbitrarily or even with some show of reason be replaced by punctuation marks, or by letters of any alphabet, or by ideographs, or by musical notes. But, seeing that the majority of papers referred to by any writer are, and in most cases will be, those of the hundred years immediately preceding the date of his own writing, I suggest that the apostrophe should be used, by those who like such self-saving devices, for all those years and for them alone. Professor Mark when he wrote in 1899 used the apostrophe for all the years 1800 to 1899. In 1901 let him use it for the years 1802 to 1901; in 1923, if, as we hope, he be still active, let him use it for the years 1824 to 1923. This plan seems to be more in accord with general usage. 'Who fears to speak of '98'? did not cease to be intelligible to everyone, until the year '98 again came round. For all years more than a hundred back, or in any case of doubt, let us use the full number; and more particularly should it be used in the dating of important letters, of publications, and of formal entries in museum registers, or similar volumes of permanent historic importance.

F. A. BATHER.

NATURAL HISTORY MUSEUM,
LONDON, ENGLAND.

A FURTHER APPEAL TO ALL LOVERS OF BIRDS.

ONE year ago all the sea birds breeding along our coasts seemed doomed to extinction at the hands of the milliners, in spite of their beauty and incalculable services as scavengers, and as guides to fishermen and mariners.

The American Ornithologists' Union, alarmed at the prospect, appointed a special committee to devise means for the preservation of these birds. This committee, aided by the press, appealed to the bird-loving public for funds with which to hire wardens to guard the sea birds while they were on their breeding grounds.

The contributions received in response to this appeal were sufficient to secure faithful wardens for the protection of all the colonies still left on the coast from Cape Charles, Virginia, northward to Maine.

The encouraging results of the efficient protection given the birds during the season of 1900 prompts the American Ornithologists' Union to continue its efforts during the coming breeding season and to extend, if possible, the work to the South Atlantic and the Gulf coasts, where there is even greater need of bird protection than in the north.

At the last session of Congress a Federal law was enacted, known as the Lacey Act, which gives by far the strongest protection ever furnished to bird or beast in the United States, as it makes it a punishable offense to export from a State any bird or animal unlawfully killed therein, or to receive such bird or animal in any other State. The common carriers are even now refusing to transport birds and animals in view of the heavy penalty attached to a violation of the Lacey law. It is believed by the committee that the vigorous enforcement

of this law by the United States Department of Agriculture, which has the matter in charge, and the proposed extension of the warden system, will in a very short time break down the whole plume trade so far as it lives upon the birds of the United States.

In addition to the special protection given to the birds by wardens, the American Ornithologists' Union, through its Protection Committee, is taking very active steps in a large number of States to improve the bird laws by amendments, or through the enactment of entirely new and effective statutes.

In view of the urgent need for a continuance of the work, and of the encouraging results of the first year's systematic efforts, the undersigned committee of the Union feel justified in making a second urgent appeal to every bird lover, and to every one who desires the preservation of these beautiful and economically valuable birds, to contribute to the fund necessary for continuing the work on a more extended scale.

Contributions should be sent to the treasurer, Mr. William Dutcher, No. 525 Manhattan Avenue, New York City.

[Signed.] Abbott H. Thayer; William Brewster, President Mass. Audubon Society; Witmer Stone, Chairman A. O. U. Com. on Bird Protection; Robert Ridgway, Curator of Birds, U. S. Nat. Mus.; C. Hart Merriam, Chief U. S. Biological Survey, Pres. A. O. U.; A. K. Fisher, Ass't Biologist, U. S. Biological Survey; J. A. Allen, Curator Vertebrate Zoology, Am. Mus. Nat. His; Frank M. Chapman, Ass't Curator Ver. Zoology, Am. Mus. Nat. His.; William Dutcher, Treasurer, A. O. U.

SHORTER ARTICLES.

THE PROPER NAMES OF THE ALPINE CHOUGH AND OF THE EGYPTIAN CROCODILE.

In a recent number of Science attention was called to some names of animals proposed by Osbeck (*Reise nach Ostindien und China*, 1765), which had been overlooked by subsequent writers and should replace several names in common use. Since then I have had the opportunity of examining a copy of the German translation * of Hasselquist's *Iter Palæstinum eller Resa til Heliga Landet, etc.*, 1757; and among the many interesting questions of synonymy that are opened by this book there are two to which I desire to call attention at the present time, viz., the proper names of the Alpine Chough and of the Egyptian Crocodile.

In the first edition (1757) of Hasselquist that author describes the Alpine Chough as *Monedula pyrrhocorax* (p. 238), which was referred to the genus *Upupa* by Linné in his *10th edition* (1758), and subsequently, in the *12th edition* (1766), described as *Corvus pyrrhocorax.* As the German translation of Hasselquist's work appeared in 1762, in which the name *Monedula pyrrhocorax* occurs with a full description on pages 238, 239, that author must be credited with first removing the Alpine Chough from *Upupa*, and restricting it under the name *Monedula pyrrhocorax* which is the proper name of the bird. Several changes in the synonymy of the species are necessary which should stand as follows:

Monedula pyrrhocorax (L.) Hass.
Upupa pyrrhocorax Linné. 1758.
Monedula pyrrhocorax Hass. 1762.
Corvus pyrrhocorax Linné. 1766.
Pyrrhocorax alpinus Viell. 1816.
Pyrrhocorax pyrrhocorax (L.) Temm. 1820.

Monedula Brehm (1828), being preoccupied by *Monedula* Latr. (1802), has been replaced by *Colœus* Kaup. Latreille's generic name must likewise fall in view of Hasselquist's prior use of *Monedula.*

The use by Hasselquist of Linné's name, *Lacerta crocodilus*, for the Egyptian crocodile has an important bearing as to the proper name of that animal. The *Lacerta crocodilus* of both editions of Linné was a composite species, and for that reason the name has been dropped by recent writers, the Egyptian species generally carrying the name *Crocodilus niloticus* Laur. 1769. It seems evident that its proper name is *Crocodilus crocodilus* (Linné), 1758, in consequence of Hasselquist's restriction of *Lacerta crocodilus* to the Egyptian animal in 1762.

I am indebted to Mr. Witmer Stone for suggestions regarding the synonymy of the Alpine Chough.

William J. Fox.
Academy of Natural Sciences,
Philadelphia.

* 'Reise nach Palästina.' Rostock, 1762.

THE WOOD BUFFALO.

THE following information has just come into my possession from the Inspector of Indian Agencies and Reserves, Mr. J. A. Macrae, who has recently returned from the far north. He writes: "At Fort Chipewyan, Fort Smith and Fort Resolution, I made close enquiries into the number of wood buffalo remaining, having an opportunity—owing to meeting so many Indians fresh from their grounds—such as I think no one else has enjoyed, to do this. Some of the Indians who were to meet me at each place had lately been near the Buffalo and had counted the different herds, which are generally speaking, three in number—one ranging from Salt River to Peace Point on Peace River; one from Salt River north to Great Slave Lake; and one from Salt River east and west. They number, I conclude, from 500 to 575. I understand that there has been an increase of perhaps a couple of hundred, and it would appear only to be necessary to continue vigorous protective measures in order to perpetuate the herd. It is noticeable that the fur of the wood Buffalo, owing no doubt to climatic conditions, is longer and thicker than was that of its brother of the plains, and it has that straightness and thickness which characterized the musk ox robe."

OTTO J. KLOTZ.

DEPARTMENT OF THE INTERIOR,
OTTAWA, CAN.

CURRENT NOTES ON METEOROLOGY.

THE 'BOOM' POPULATION OF KANSAS.

SOME interesting facts concerning the change in the number of inhabitants of Kansas as a result of the rise and collapse of the 'boom' of the latter part of the decade 1880–1890, are given by Gannett in an article on 'The Population of the United States' in the last number of the *Bull. Amer. Geog. Soc.* (No. 5, 1900). It will be remembered that a succession of unusually rainy seasons at that time was followed by a large increase in land values, the whole region witnessing a tremendous 'boom.' There was a rapid gain in population. A number of dry seasons following, the settlers were literally starved out, and the country was quickly depopulated again. In 1885, at the beginning of the 'boom,' Kansas had a population of 1,268,530; in 1888, near its crest, the population numbered 1,518,552; in 1890 the figures were 1,427,096, and in 1895 only 1,333,734. The State thus gained nearly 250,000 inhabitants in three years, and later lost nearly 200,000. Similar conditions obtained in Nebraska and the two Dakotas.

THE METEOROLOGY OF LOWER CALIFORNIA.

IN an article on 'Explorations in the Central Part of Baja California,' in the *Bull. Amer. Geog. Soc.* (No. 5, 1900, 397–429), Dr. Gustav Eisen gives a brief account of the rainfall and climatic conditions of the meteorologically practically unknown peninsula of Lower California. There are two sources and two seasons of rainfall. The summer rains extend from Todos Santos and Cabo San Lucas, in the south, as far up as the Sierra Nevada, in the northern part of Alta California. These summer rains are most frequent and heavy in the backbone of the Sierra which runs along the eastern coast of Baja California. The winter rains now and then extend from Alta California down to the Pacific Coast, even as far south as San José del Cabo. These winter rains never enter the Gulf of California, and diminish in quantity and regularity to the south. As far south as San Quentin they are fairly regular, but beyond that point they are uncertain. In spite of these two sources of supply, the peninsula of Lower California is but very scantily supplied with rain.

THE HARVARD METEOROLOGICAL STATIONS IN PERU.

THE 55th Annual Report of the Director of the Astronomical Observatory of Harvard College contains an announcement which will fill meteorologists the world over with regret. Speaking of the meteorological stations of the Harvard College Observatory in Peru, concerning which mention has frequently been made in the columns of SCIENCE, Professor Pickering says: "The observations at these different stations have now been continued in many cases for eight or ten years. At such stations, where, from the necessities of the case, the observers are generally men of limited education and experience, observations of the greatest accuracy cannot be expected, except by maintaining trained observers at greatly in-

creased expense. * * * Taking into consideration the striking uniformity of conditions which prevail in different years in this region, it is probable that additional observations would not greatly increase our knowledge. It has been decided, therefore, to suspend, at the end of the year 1900, the meteorological observations of all the stations, except those at Arequipa.''

RECENT PUBLICATIONS.

C. F. MARVIN: *Anemometry*. U. S. Department of Agriculture, Weather Bureau. Circular D, Instrument Division. 2d Edition. Washington, D. C. 1900. 8vo. Pp. 67.

This is a circular of general information respecting the theory and operation of instruments for indicating, measuring and automatically recording wind movement and direction, with instructions for the erection and care of such instruments of the Weather Bureau pattern.

C. F. MARVIN: *Psychrometric Tables for Obtaining the Vapor Pressure, Relative Humidity and Temperature of the Dew-Point*. U. S. Department of Agriculture, Weather Bureau. Washington, D. C. 8vo. 1900. Pp. 84. Price, 10 cents.

These are the tables for the reduction of the psychrometric observations at the regular and volunteer stations of the Weather Bureau. The use of these tables began Jan. 1, 1901.

NOTES.

DR. H. R. MILL has become the Editor of *Symons's Monthly Meteorological Magazine*, in place of Mr. H. Sowerby Wallis, who has held that position since the death of Mr. G. J. Symons.

ACCORDING to Professor A. J. Henry (*Monthly Weather Review*, Oct. 1900), a conservative estimate of the total loss of property by lightning in the United States during the year 1899 would probably be $6,000,000.

R. DEC. WARD.

THE NAVAL OBSERVATORY IN CONGRESS.

THE Observatory was discussed in the Senate on January 22d in view of an item in the naval appropriation bill. Mr. Morgan said:

I want to call the attention of the Senate to the fact that this great Observatory is without any real organization in law, and it is a haphazard, piecemeal sort of arrangement by which it has been put under the Navy Department. It was first called the National Observatory of the United States. It was afterwards called the Naval Observatory of the United States, and was put under the Navy Department. No head or management of the Observatory, as I understand it, has ever been appointed or given the direction of it, but an officer of the Navy is detailed to take charge of the Observatory from time to time, who controls this matter. However, it is not a military office in any sense of the word, and it does not follow that a man educated at Annapolis has any very special training in astronomy. It seems to me that that great institution is very badly crippled for want of a proper organization.

We have here, upon the recommendation of what is called the chief astronomer, a provision by which an assistant spectroscopist is to be appointed, and yet they have made no reports recently of any work of that kind in the Observatory. I suppose there must be work of that kind going on, but the reports ought to show it if they are of any value at all

Now, this great Observatory, perhaps the largest national observatory in the world—I think it is the largest one in the world—not larger, perhaps, though more costly, than some of the private observatories—has cost the Government of the United States for the site, buildings, grounds, and outfit $655,845, and the roads, pathways, and gradings, $95,900, making a total cost of $751,745.

As I understand it, the Observatory does not have the rank amongst the observatories of the United States that it ought to have. There is very valuable work done there, a great deal of it, no doubt, but simply for the want of proper organization the work has not been conducted in the way it ought to be. I have introduced a bill in the Senate to organize the Observatory, for it has never had any organization.

I wanted to call the attention of the chairman of the committee to this particular appropriation, with a view of drawing out some expression from him, or from some one who is informed particularly on the subject, about certain points. Congress, it seems, has neither defined the objects for which the Observatory was founded, made any provision for its control, or appointed any authority to determine what it should do or to report upon its work, nor assigned to it any public function. What the Navy Department has been able to do is to provide for its government as a naval station, appoint an officer to command it, detail professors in the Navy for duty, give to the senior of these professors the title of astronomical director, and charge him with the duty of determining what astronomical work shall be done. But, as far as known, it has never been able to provide the head of the es-

tablishment, or the astronomical director, with any instructions or suggestions as to what the Observatory should do.

I am willing that this assistant spectroscopist shall be appointed and that he shall have the salary proposed to be paid under this proposed act, at the present time, because it seems that everything which is suggested here by a naval officer who is connected with the Observatory goes without any regulations of law at all. There is no law to regulate the National Observatory.

Mr. Chandler said :

When the naval appropriation bill comes up I hope the Senator will aid myself and the committee in securing some appropriate legislation to improve the management of the Observatory ; but it is not proposed by that bill to take the Observatory wholly away from naval control. It is proposed to establish a permanent board of visitors, on which shall be some of the most eminent astronomers, and also to make the astronomical corps a corps of civil officers, instead of a corps of life officers in the Navy. There are other incidental improvements of administration which are recommended. I hope there will be some legislation on the subject.

There is not, I will add, perfect satisfaction among the astronomers of the country with the work of the National Observatory ; and it was that dissatisfaction which led to the appointment of this board of visitors.

The subject is worthy of the very careful consideration of the Senate and of Congress.

Mr. Allison said in reply to Mr. Morgan :

I agree with the Senator that it may be necessary to reorganize the Naval Observatory. That has been in contemplation for some years.

On January 25th the same question was raised in the House, sitting as Committee of the Whole in connection with an item in the naval appropriation bill, appropriating $18,000 for the building of three houses for the astronomers of the observatory. Mr. Newlands said :

I would like to ask the gentleman from Illinois whether he has any views in regard to the taking of this observatory out of the control of the Navy Department? My information is that it is really of no scientific value to the country or to the world, and that the observatory would be much better administered by some other department of the Government, with really scientific men at its head, instead of naval officers detached for duty there.

Mr. Cannon. The gentleman asks me a question of policy that is not necessarily connected with the building of these houses. I would say to my friend that no doubt my friend from West Virginia would not agree with me. I do not believe, to answer his question, that the Astronomical Observatory ought to be under the control of the Navy or the Army or any other department in Washington. I think that we should have better administration and more economic administration if we were rid of that expensive house out there [the superintendent's house] under a direction that does not direct in scientific lines.

Mr. Newlands. I wish to state to the gentlemen that I understand that the naval observatory in England is of great scientific value, not only to that country but to the world, for the reason that the men in charge of the observatory are trained scientific astronomers and not naval officers. Now, I would call his attention to that and ask him whether it is not advisable that this entire department of the Government be placed under scientific control, with a view to the advance of scientific information.

Mr. Cannon. I will say to my friend now, if he will not call on me for names, because I do not like to give these in a city of official direction—I will say to him that men who have been in the service, scientific men, astronomers of this Naval Observatory, and men I apprehend that are in its service now, have protested to me time and time and time again that it was not so efficient as it ought to be ; that it was under a direction that was not in harmony, but that with less expense more efficiency could be had.

Subsequently Mr. Dayton described in some detail the work of the Board of Visitors to the Observatory of which he was a member. He said :

We went over, as far as was possible, as thoroughly as possible, the condition of the Naval Observatory and its management and its cost, and the result of our investigation is embodied in the report which I hold in my hand. We took occasion to investigate its history from start to finish and its management from start to finish. In addition to that, in order that there might be full and complete information presented to Congress and the country, certain questions set forth in this report were sent to almost every astronomer of reputation in the country.

Among those questions was one whether or not this Observatory should be transferred from the Navy Department to some other department, whether its efficiency would be promoted by such transfer, and whether, if such transfer was made, with what Department this Observatory should be connected. The answer to these questions presented an anomalous state of affairs. There was an absolute division of opinion that was nearly equal. For instance, my recollection is that 19 of the prominent astronomers suggested thought it ought to be disconnected from

the Navy Department, and 19 said no; but when it came to their suggestions as to what department it should be connected with, if disconnected from the Navy Department, the disagreement was enough—not to speak too lightly—to make any man's head ache.

There was almost as wide a divergence of opinion as opinions expressed. Some suggested the Treasury Department, some suggested the Geological, some the Interior Department, and some the Smithsonian Institution. Many thought—and I am sure the gentleman from Illinois would not be in favor of it—that it was immediately necessary to establish a new department of the Government, that of a department of science, and for the appointment of a secretary of that department, in order that this Bureau and this Observatory and one or two others might be connected with it and embodied in one institution. Others suggested that it was necessary for the Government in order properly to administer the Observatory to establish a national university.

This board, composed, as I say, of a member of the Senate and a member of the House and these three representative astronomers, after considering the whole matter from one end to the other, reached the conclusion that in the absence of the department of science or of the national university the management of the Observatory could be and would be as properly carried out under the control of the Navy Department as any other and at a probably less expense than any other.

Now, as I stated a moment ago, the Observatory work is done, as far as the executive head is concerned, by an officer detailed from the United States Navy, but who does not have control of the astronomical work. To a certain extent he is the head of the Observatory, but the responsibility for the astronomical work is placed upon the astronomical director.

The question whether or not it would be better for the head of the institution to be an astronomer, either from civil life or from the corps of mathematics, is one which can not in this connection be determined. But, so far as the scientific work is concerned, I am satisfied that it is now being well done; and I want to call attention to the fact that in a two-page article in SCIENCE of recent date, criticising Captain Davis's report to the Secretary of the Navy, it is admitted that the work is well done so far as the scientific part of it is concerned.

Therefore, I am sure my friend from Nevada [Mr. Newlands] will not hereafter desire in any way to do injustice to an institution of this country which may stand at the head, and should stand at the head, of all similar scientific institutions throughout the world.

SCIENTIFIC NOTES AND NEWS.

AN American Association of Pathologists and Bacteriologists was formed at a meeting held in New York on January 26th. The following officers were elected: *President*, Dr. W. T. Councilman; *Secretary*, Dr. H. C. Ernst; *Treasurer*, Dr. Eugene Hodenpyl. The first regular meeting of the Society will be held in Boston on April 5th.

ON the occasion of the retirement of Sir Archibald Geikie, F.R.S., of the Geological Survey of Great Britain and Ireland, he will be entertained at a dinner and presented with an address.

AMONG the honors conferred on the occasion of the bi-centenary of the Prussian monarchy is the patent of hereditary nobility to Dr. Emil Behring, professor of hygiene and the history of medicine at Marburg.

WE learn from *Nature* that the Manchester Literary and Philosophical Society has awarded the Wilde medal for 1901 to Dr. Elias Metchnikoff, of the Institut Pasteur, Paris, for his researches in comparative embryology, comparative anatomy, and the study of inflammation and phagocytosis; and the Wilde premium to Mr. Thomas Thorp, for his paper on grating films and their application to color photography, and other communications made to the Society. The Dalton Medal for 1901 has not been awarded.

THE Maximillian order for science and art of Bavaria has been conferred on Dr. Hugo Seeliger, professor of astronomy in the University at Munich.

PROFESSOR R. BLANCHARD, who for twenty-three years has filled the position of secretary to the Zoological Society of France, has presented his resignation to take effect on the twenty-fifth anniversary of the foundation of the Society. On this occasion a commemorative medal will be conferred on Professor Blanchard in recognition of his great services to the Society.

MR. W. H. DINES has been appointed president of the Royal Meteorological Society, London.

PROFESSOR GEORGE E. HALE, of the Yerkes Observatory, gave an address before the Boston

Society of Arts on January 31st, on 'Astronomical Photography with the Great Visual Telescope of the Yerkes Observatory.'

DR. C. W. ANDREWS, of the Geological Department of the British Museum, has, on account of ill health, been granted leave of absence for three months, which he proposes to employ in studying the geology of Egypt and the Soudan. It is earnestly hoped that he may be able to return to his excellent work on fossil reptiles and birds.

PROFESSOR W. B. SCOTT, of Princeton University will deliver a course of sixteen lectures before the Wagner Institute in Philadelphia, the first one to be given early in February.

THE officers of the Entomological Society of London have been elected as follows: *President*, the Rev. Canon Fowler; *Treasurer*, Mr. Robert McLachlan, F.R.S.; *Secretaries*, Mr. Herbert Goss and Mr. H. Rowland-Brown; *Librarian*, Mr. George C. Champion; and as other *Members of Council*, Professor T. Hudson Beare, F.R.S., and Messrs. R. Adkin, Charles G. Barrett, William L. Distant, H. St. J. Donisthorpe, Charles J. Gahan, Robert W. Lloyd, Edward Saunders, G. H. Verrall and Colbran J. Wainwright.

THE Geological Society of France has elected the following officers for the year 1901: *President*, M. Carez; *Vice-Presidents*, MM. Haug, van den Broeck, Dereims, Nicklès; *Secretaries*, MM. Gentil, and Pervinquière; *Vice-Secretaries*, MM. Giraud, Mémin, *Treasurer*, M. Léon Janet; *Librarian*, M. Ramond.

WE regret to record the death of Mr. Frederic W. H. Myers, which occurred on January 17th at Rome, where he had gone, we understand, at the invitation of Professor William James. Mr. Myers was an accomplished poet and man of letters, but is best known to the general public for his enthusiastic devotion to the cause of psychical research. Mr. Myers was born in 1843, being a son of the Vicar of Keswick, and was elected Fellow of Trinity College, Cambridge in 1865. Since the establishment of the Society for Psychical Research in 1882, he devoted himself largely to its work, being its honorary secretary. He was one of the authors of 'Phantasms of the Living,' and has left ready or nearly ready for publication a work on 'Human Faculty.'

DR. SEDGWICK SAUNDERS, the medical officer of health and public analysis for the city of London, and the author of numerous contributions to hygiene and public health, died on January 18th, at the age of seventy-six years.

CONSUL GENERAL MCNALLY has reported to the State Department the death of Miles Rock, in Guatemala. Mr. Rock was born at Ephrata, Lancaster County, Pa., October 10, 1840. He was graduated from Lehigh University, in 1868 as civil engineer. From 1868 to 1869 he taught mathematics and mineralogy at Lehigh University. In 1870 went to the observatory at Cordova, Argentine Republic as astronomical assistant to Dr. B. A. Gould. remained in Cordova for three years, mapping the stars of the Southern heavens. From 1874 to 1877 he was employed by the United States hydrographic office, determining latitude and longitude in the West Indies and Central America. In 1878 he was an assistant on the Wheeler survey west of the 100th meridian, determining latitude and longitude, and from 1879 to to 1883 he was assistant astronomer at the United States Naval Observatory at Washington, and observed the transit of Venus at Santiago in 1882.

THE five series of Alaskan birds secured at Point Barrow by Mr. E. A. McIlhenny has been divided into several representative collections. Most of these have now been disposed of, the best ones going to the Academy of Natural Sciences, Philadelphia, to the Hon. Walter Rothschild, Tryng, England, and to the Carnegie Museum at Pittsburg, Pa.

THE Board of Estimate and Apportionment of New York City has approved the plans and specifications of the New York Public Library building, and appropriated $2,850,000 for its erection. This is in addition to the $540,000 already appropriated for the removal of the old reservoir and the building of vaults. The total cost of the library will consequently be $3,390,000. It has been decided to build the library of white marble which adds about $400,000 to the original estimate.

MR. ANDREW CARNEGIE has offered to give

$50,000 to Lewiston, Me., for a public library on condition that the city will provide a site and $5,000 annually for its support.

THE Detroit Branch of the Archeological Institute of America, held its annual meeting in January. During the past year 64 new members were admitted and the fund contributed to the Institute reached $1,042. The New York and Boston branches are now the only ones surpassing the Detroit branch in membership and activity. The committee, appointed to take steps for an archeological survey of Michigan, was increased to five, with instructions to work for the passage, at the present session of the Legislature, of a bill appropriating $2,500 annually for investigating the antiquities of Michigan.

THE Turin Academy of Sciences will award, at the end of the year, its Bressa prize, of the value of nearly $2,000, for the most important investigation or invention made during the past four years.

THE Röntgen Society, London, offers as a gift from its president, Dr. J. Macintyre, a gold medal to be awarded to the maker of the best X-ray tubes. They must be forwarded to 20 Hanover Square, London, so that they arrive not later than May 1st of the present year.

SOME of the specimens in the Virchow collection in the Pathological Museum of the University of Berlin were destroyed by a fire on January 16th.

IN the House of Representatives, on February 1st, Mr. Southard, of Ohio, chairman of the Committee on Coinage, Weights and Measures, asked unanimous consent to consider a bill to establish a national standardizing bureau. After some discussion it was agreed that the bill should be made a continuing order after the disposal of the bill to promote efficiency of the revenue cutter service.

THE New York State Medical Society, meeting at Albany, has passed the following resolution:

Whereas, Believing that the citizens of the State of New York, and liberal-minded men everywhere, are to be congratulated upon the establishment of the Pathological Institute of the New York State Hospitals, an institution founded for the investigation of the problems connected with insanity and related diseases and unique in the annals of medicine for the greatness of its opportunities, and most strongly recommending that the work of investigation for which the Institute was founded be sustained along its present lines of organization and principles of research;

Therefore be it resolved, That we, the members of the Medical Society of the State of New York, respectfully request his Excellency the Governor to sustain the Pathological Institute of the New York State Hospitals; that we beg him to give his support to its growth and development; to protect it against further difficulties, and that we submit to his attention protests against the subversion of the work of the Pathological Institute along the lines laid out by the director, the work being upheld by a wide movement of the medical profession and prominent scientific men of this country and of Europe.

THE Forest, Fish and Game Commission bill introduced into the New York Legislature to carry out the Governor's recommendation, and abolishing the Fish and Game Commission, and turning its powers over to the Forest Preserve Board, was reported favorably in the Senate, amended so as to abolish the Forest Preserve Board, and substitute for the present Forest, Fish and Game Commission, a commission of three similar to the proposed new Prison Commission. One member of the commission will receive a salary which has been fixed at $5,000. The other two will be selected from among the constitutional State officers, one of whom, it is agreed, will be Lieut.-Gov. Woodruff.

At the monthly general meeting of the Zoological Society of London on January 18th, it was stated that there had been 211 additions made to the society's menagerie during the month of December, amongst which special attention was directed to seven specimens of Verreaux's guinea fowl (*Guttera edouardi*), presented by J. F. Walker, of Bulawayo; and to a valuable series of Indian birds lately presented to the society by Mr. E. W. Harper, F.Z.S., of Calcutta, consisting of examples of 20 species all new to the Society's collection. It was further stated that during the past month 20,931 persons had visited the Society's gardens, showing an increase of 6,605 as compared with the corresponding period of 1899.

MR. C. COLERIDGE FARR, in charge of magnetic work in New Zealand, has sent a letter to the editor of *Terrestrial Magnetism* in regard to the magnetic observatory soon to be erected at Christchurch, approximately in latitude 43° 30′ S., and longitude 172° 38′ E. New Zealand will owe this observatory to the labors of a committee, of which Mr. Farr is secretary, appointed at the beginning of last year by the Australasian Association for the Advancement of Science. It will be the most southerly observatory in the world and will have an ideal situation in a magnetically uniform district, except for the possibility of disturbance by electric tramways, which, however, is not likely to occur, for some years and may be prevented altogether by legislation. It is hoped that the observatory will be in operation by the end of this year. Dr. Chree has undertaken the supervision of the construction of the magnetographs by Adie. Mr. Farr invites the various Antarctic expeditions that are soon to leave Europe to make any use they care to of the observatory, and expresses his willingness to give magnetic information or any other assistance. The Lyttelton Harbor Board has offered dock accommodatian to the British National Expedition, and Mr. Farr thinks would doubtless extend the same courtesy of other expeditions. Another result of the labors of the above-mentioned committee is a small appropriation by Parliament to carry out some sort of magnetic survey of New Zealand. The Kew Observatory Committee has aided the work by the loan of a set of absolute instruments, with which observations have so far been made at 100 stations, chiefly in the middle island. In this Mr. Farr was ably assisted by Mr. H. F. Skey.

THE *British Medical Journal* reports that in the Budget of the Italian Minister of the Interior there will be included a sum of money for the prosecution of the campaign against malaria, which has already been begun in various parts of Italy under the influence of the experiments of Professors Celli and Grassi. This money will be devoted by the Government to the carrying out of new experiments and the establishment of prizes. The Italian parliament has before it a bill for the prevention of malaria, by which it would be made compulsory on all employers of labor in malarial districts to make provision for the lodging of laborers with proper precautions against infection in accordance with the present state of knowledge. They would further be compelled to supply remedies gratuitously to laborers who contract the disease until they have recovered their health. They would also have to build suitable dwellings for their laborers and proper lodging places for casual hands, all properly protected against malaria. Loans at 3½ per cent. would be advanced out of the public funds to small proprietors in order to enable them to comply with the obligations placed upon them by the bill. There is a clause exempting from taxation for twenty-five years new buildings erected for industrial purposes in malarial regions. Another clause provides that indemnities at fixed rates are to be paid to sick laborers and to their families by employers who fail to comply with the requirements of the bill.

THE *Evening Post* states that in consequence of the growth of German trade and commerce in all parts of the world, the German Emperor has decided to establish an institute for the study of oceanology, in Berlin, in connection with a naval museum. Both are to be part of the Berlin University, and will serve as an academy for naval instruction on the most modern system and in the widest sense of the word. One of the main objects is the instruction, not only of students in the subjects dealt with, but of all persons interested in them, including ships' captains, ship-owners, merchants, etc. The museum will be formed on a very large scale, the Emperor having ordered that all the naval collections at Wilhelmshaven, Dantzic, Kiel, and Hamburg shall be brought to Berlin, as well as all special collections in other museums, and the greater part of the German naval section exhibited in Paris last year. The Emperor has allotted two hundred and fifty thousand Marks for this purpose, and the Prussian Landtag has also made an appropriation. Though the institutions are still in course of formation, a series of free public lectures on oceanology, etc., by several of the leading German professors will be started at once. The program includes lectures on 'History and the Influence of Navigation,'

'The German Deep Sea Expedition,' 'The Polar Oceans and their Discovery,' 'Astronomy and Navigation,' 'The History and Use of Warships,' 'Oceanology and Navigation,' 'The Influence of Sea Power in History,' etc.

UNIVERSITY AND EDUCATIONAL NEWS.

BY the provisions of the will of the late Benjamin D. Silliman, $110,000 will ultimately revert to Yale University and $10,000 to Columbia University. Yale University has also received from an anonymous donor $100,000 for a new building for the medical school and $6,000 from the family of the late Robert Callender, class of 1898, to found a scholarship.

JOHN D. ROCKEFELLER has agreed to give $15,000 each to Mercer College, at Macon, Ga., Carson Newman College, at Mossy Creek, Tenn. and Des Moines College, at Des Moines, Ia., on the condition that each will raise subscriptions of $60,750, to be paid in four annual payments.

THE Assembly of the State of California on January 29th passed the bill conferring full corporate powers and privileges on the trustees of Stanford University.

A SPECIAL committee of the Alumni of Stanford University, appointed last November, reported on January 26th, to a meeting of the alumni at San Francisco on the case of Professor Ross. The Committee calls attention to Professor Ross's pamphlet entitled 'An Honest Dollar' illustrated by political cartoons, published during the campaign of 1896, and states that Mrs. Stanford regarded this as undignified. The report continues:

> The justice of the criticism expressed at the time the pamphlet was published must be deemed to be conceded by Dr. Ross, since it has been admitted by him to your committee that he would not again pursue the same course under similar circumstances.
>
> Your committee has been unable to find any evidence that Mrs. Stanford ever took exception to Dr. Ross's economic teachings.
>
> That her ultimate demand for his resignation was not due to opinions expressed in his speeches on 'Coolie Immigration' and the 'Twentieth Century City,' but was because she deemed that her original estimate had proved correct and that he was re-displaying, after three years of trial, those qualities found objectionable in the instance of her original action.
>
> The admission of Dr. Ross to your committee that he would not regard a university rule against the participation in politics by a university professor of economics during the progress of a political campaign, as impairing the proper right of academic freedom, disposes of his contention that the criticism of his conduct in 1896 is capable of that construction.
>
> From the foregoing facts and upon the testimony as a whole your committee concludes that the action of Mrs. Stanford in asking the dismissal of Dr. Ross involved no infringement of the right of free speech.

The London *Times* devotes to the troubles at Coopers Hill College an editorial which begins as follows: "The Secretary of State for India will be guilty of a grave and lamentable error if he is induced by the promptings of official pedants to refuse the demand for inquiry into the recent dismissals at Coopers Hill College, so vigorously pressed in Lord Kelvin's succinct and forcible letter published in our columns on Saturday last. It is well to remember that one of the causes which contributed to the downfall of Mr. Gladstone's powerful administration in 1874 was Mr. Aryton's insolent treatment of men of science. His contemptuous reference to his intellectual superiors, Sir Joseph Hooker and staff at Kew, as 'gardeners' placed a black mark against the name of the First Commissioner of Works of that day which was never obliterated and which drove him out of political life. The man in the street may not understand much about science, but he has a feeling of respect for scientific men who work for small rewards in the interests of truth and knowledge. The public is quick to resent injustice inflicted on a class who have little power of defending themselves and whose services are of enormous and increasing value to national progress."

IT is reported in the papers that serious riots have occurred at Kieff University. Conflicts have taken place between the students and Cossacks, in which many of the former were killed or wounded.

DR. RICHARD EWALD has been promoted to a full professorship of physiology in the University at Strasburg.

*PHYSICS AND FAITH.**

OUR knowledge concerning the properties of and changes in matter is gained in the first place through our bodily senses, and secondly through the intellect; the primary concepts thus acquired are confirmed, modified and enlarged by operations of the imagination and of the reason. The five senses with which we are endowed are of very unequal value in the acquisition of knowledge of natural objects; smelling, tasting and hearing make but small and unimportant contributions compared with those communicated by the senses of sight and of feeling.

An intelligent being, having only the single sense of feeling, would nevertheless be able to handle a large number of objects within his reach and to study their properties; he would early distinguish between matter at rest and matter in motion; he would notice the properties of inertia and of weight; he would perceive in his person the effects of heat and of cold, of dryness and of moisture; he would become acquainted with the shape of bodies of moderate size and with their superficial properties, such as smoothness or roughness, softness or hardness; he might, if he made sagacious use of his one power, recognize the distinction between matter in its three states—solid, liquid and

* Address of the retiring President of the Chemical Society of Washington, February 14, 1901.

gaseous, though it would be difficult for him to comprehend their relations to one another. Air in motion makes itself felt, but of gaseous matter in general his knowledge would be very limited and vague. The simplest of tests would make him acquainted with elasticity, malleability and ductility, as well as with density and tenacity; fusibility and solubility would undoubtedly greatly puzzle him, and he would of course remain ignorant of light, of sound and of the physical universe beyond his limited sphere.

If to this being of one sense the so-called 'chemical senses' of taste and of smell were added, he would acquire greater insight into the special qualities of bodies that affect these organs; he would observe the agreeable odors of the natural products of the soil and forest as well as the offensive ones in the three kingdoms of nature; he would learn to differentiate many gases previously regarded as identical; he would learn to distinguish between alkaline and acid, sweet and bitter substances, and to recognize those having particular flavors. On the other hand, the intelligent being of three senses would fail to comprehend the physiological processes by which the sensations are perceived, and in this respect he would be little less ignorant than are beings of five senses.

On endowing this imaginary person with the sense of hearing his knowledge of the external world would be greatly enlarged and his personal comfort increased, he would also acquire a more exact knowledge of some of the properties of matter; he would become conscious of vibrations in the air conveying sounds, and by listening to the roar of a Niagara or to the chirp of a cricket, to the melodies of song birds or to the fierce growl of a beast of prey, he would attain to more lofty ideas of the marvels of nature than in his deaf state. He could now learn of the crackling of brimstone, the 'cry' of tin, the snapping of electric sparks, and the startling detonations caused by combustion of 'villainous saltpetre' and of certain gaseous mixtures.

If finally, the precious gift of sight should be bestowed upon the subject of four senses a new world would be opened to him, and his intellectual and emotional capacities would be enhanced immeasurably; for the first time he would be able to realize the full meaning of the word beautiful as applied to nature. With the fifth sense he would perceive the beauty of form, of color, of luster, of ornamentation in the flower, the bird, the insect, the floating clouds and in the rainbow; he would have opened to him the magnificent spectacle of a starry firmament, of an aurora and of the sun in its noon-day glory. He would now be fairly equipped for investigating physical science.

At a remote period *seven* senses were attributed to man; these are given by the Hebrew author of the ancient book Ecclesiasticus as seeing, hearing, tasting, feeling, smelling, understanding and speech. They are referred to by the poet Pope in the couplet:

"Good sense which only is the gift of Heaven,
And though no science, fairly worth the seven,"

and the idea survives in the singular phrase in common use: 'Frightened out of one's seven senses.'

The nature of a sixth sense has been a matter of speculation, but it is hardly less difficult for individuals with five senses to form a conception of an extra sense, than it is for a sightless person to acquire any adequate idea of the true significance of seeing. The sixth sense has been called the muscular sense as distinguished from touch, but we prefer to think of it as a sense for cognizing forms of energy whose seat of action lies in the ether supposed to pervade space.

While it is absolutely impossible for a finite mind to plan the structure of an or-

gan that would give us this power or to conjecture its mode of action, in discussing it, we find it convenient to use terms analogous to those that we employ for the eye. We need, then, a keen sense that will enable us to 'see' what takes place in the interior of masses in their several states of aggregation; to 'see' the arrangement of the atoms within the molecule, and to study their behavior under the influence of well-known as well as obscure forms of energy. Even as Röntgen rays force a passage through the intermolecular voids of certain kinds of masses, a sixth sense might enable us to 'see' the action of heat in separating the molecules and the influence of chemism in uniting or in parting the atoms within them; to perceive the mechanism of solution, to 'see' the infinitesimal particles of sodium chlorid penetrate the aqueous liquid to form a homogeneous solution. To 'see' the exact manner in which an electrical 'current' (so-called) exerts its separating power when brought to bear upon a liquid; to test whether the theory of ionization has any substantial foundation. A sixth sense might permit us to 'see' the energy manifested by the Hertzian waves which under the skilful management of Marconi are just beginning to serve the interests of man; to learn the secrets of that medium permeating interstellar and intermolecular space which becomes the adjunct of sight; the art of photography has made visible views of the interior of masses impermeable to rays of light and has yielded permanent records of the sound waves of the air, but we seem to need a sixth sense to cognize the operations of the luminiferous ether.

In the fantastic conception in which we have indulged the imaginary being is supposed to be intelligent, for mere sense-perception without the cooperation of the intellect could not augment one's knowledge of the physical universe to any great extent. Through our bodily senses we learn the existence of natural phenomena, but it is through operations of the intellect that we acquire the deeper knowledge which becomes the subject of imagination, of reason and, eventually, of faith.

After observing that some kinds of matter suffer changes in form, in properties, in potential energy when subjected to the influence of heat, of light, as well as to the action of other kinds of matter, and that certain causes produce uniformly identical results, thinking men made endeavors to explain the phenomena by inventing hypotheses as to the essence of the material objects and of the various kinds of energy acting upon them. In the infancy of learning, Greek philosophers of wonderful intuition conceived a theory of the constitution of matter that has made a lasting impress on physical science; the theory possessed marvelous adaptability, and when a Manchester schoolmaster grafted upon the aged trunk the tender shoot of his genius, it soon grew to be a vigorous branch that bore fruit of unsuspected value. Nearly a century has elapsed and the atomic theory has secured a strong hold upon the minds of physicists and of chemists; maintained by men of sound judgment and great authority, imparted by teachers of recognized ability to successive generations of pupils, it has become a matter of belief, adopted with a few exceptions by scientists throughout the enlightened world, and in their hands it has become a potent factor in the progress of physical science. Yet this theory is purely a figment of the imagination and makes extraordinary assumptions difficult of credence; it supposes that matter is made up of very minute particles, indivisible, indestructible, and unchangeable, separated from one another by void spaces larger than the particles themselves; these diminutive atoms are of definite, uniform and constant figure, and are in perpetual motion in all

conceivable directions at exceedingly high rates of speed; moreover, the atoms composing the different chemical elements are of determinate weights corresponding to their equivalents of combination; these minute particles attract each other with varying degrees of strength and unite in simple ratios to form larger particles called molecules; agglomerations of these molecules constitute masses, visible to the eye and subject to the laws of mechanics.

Faith in this purely intellectual conception has enabled men of genius to refer to it the explanation of many facts, and the hypotheses resulting have developed into laws of prime importance in chemical philosophy; Dalton discovered facts in the union of chemical bodies whose interpretation he found in the doctrine of atoms; Humboldt and Gay-Lussac reinforced the Daltonian laws by their labors on the ratios in which the volumes of gases combine; Avogadro, by purely physical researches established the relation between the volumes of gases and the number of their constituent molecules; and Gerhardt, working in the field of organic chemistry, observed the bearing of these discoveries on chemical philosophy and, by clearly establishing the distinction between atom and molecule, gave to the atomic theory its modern aspects.

Faith in this theory has made it possible to devise a scheme of notation that in spite of its defects has proved of great utility in promoting the advancement of chemistry; the multitudinous problems of stoichiometry, the modern theories of solution and of electrolysis, the doctrines of isomerism and of stereo-chemistry are achievements of the intellect and of the reason based upon a belief in an imaginary condition of matter. To crown the whole, Newlands, the Englishman, originated, Meyer, the German, and Mendeléeff, the Russian, brought to a high state of perfection, the Periodic law which has given to chemistry that prophetic power, long regarded as the peculiar dignity of its sister science, astronomy.

Quite apart from these abstract principles, based upon a belief in the atomic constitution of matter, is the practical side of the question, of which the analytical chemist avails himself in determining the value of substances submitted to him; on the results of his figures thousands of dollars may change hands in the manufacturing, mining and commercial world. A ship-load of material is bought and sold on the result of the analysis of a sample conducted by a chemist, who bases his procedure on the supposed numerical relations of the invisible, intangible, immeasurable particles he calls atoms and in his calculations he relies on the constants determined by others, in whom he has confidence, and the accuracy of which constants he has to accept on faith. Reliance on the *dicta* and *data* of investigators whose very names may be unknown lies at the very foundation of physical science, and without this faith in authority the structure would fall to the ground; not the blind faith in authority of the unreasoning kind that prevailed in the middle ages, but a rational belief in the concurrent testimony of individuals who have recorded the results of their experiments and observations, and whose statements can be verified.

This faith in the fundamental principles of physical science persists notwithstanding it encounters insurmountable difficulties. Many problems defy the efforts of materialistic philosophers to solve them; the origin of matter and of motion; the initial source of energy as well as the relation of gravitation to other forces; the positive nature of the interstellar ether imagined as a vehicle for the transmission of light, not to mention proofs of its existence; the true inwardness of actinism, of Röntgenism, and of the rays named after Becquerel; the ultimate identity in es-

sence of the so-called elementary bodies. Some of these problems will undoubtedly be solved as knowledge of the material world increases, but others are destined to remain inscrutable to finite minds and as such may be called scientific 'mysteries.' We can construct ingenious arguments based largely on assumptions, and reason ourselves into the notion that our hypotheses explain the questions at issue, but after all we know very little beyond the effects observed.

These problems arise in every department of organized knowledge; the student of chemistry does not have to look far afield to encounter mysteries, though he does not commonly so style them; phenomena of ordinary experience challenge the interpretation of philosophers. What do we actually know of the chemical force called affinity? Who can tell why the attraction between A and B is so much stronger than between A and C, or why one element forces another out of its combination with a third? What chemist who has watched under the microscope the beautiful, symmetrical manner in which minute particles of a substance separating in solid form from solution, arrange themselves in geometrical figures obeying well established mathematical laws, can pretend to explain the cause of the astounding behavior of the inert, lifeless matter?

But I desist from propounding further queries, the answers to which are buried in impenetrable mystery. A student of elementary chemistry, impressed with the ability of the teacher to explain natural phenomena, asked him: 'Professor, why is gold yellow'? Whereupon the professor, waiving the customary explanation [?], reverently answered: 'Because God made it so!'

Is it unfair to scientists to say that they sometimes take refuge in obscure language to veil their ignorance? It may help our imagination to affirm that carbon and other elements occur in 'allotropic' forms, but does this statement adequately explain the phenomenon? To term the peculiar action of certain bodies, which themselves suffer no change while they effect decompositions or combinations in others with which they are brought in contact, as 'catalytic' may be soothing to the mind, but is it scientific? Is it satisfactory? One hundred and fifty years ago the properties of water were said to be caused by its 'aquosity'!

In this study we have confined our illustrations to the physical and chemical branches of science, but they might well be drawn from astronomy and from the biological sciences; in the former, one becomes acquainted with

"Realms yet unrevealed to human sight,"

as well as with the conception of infinity in space and in time; in the latter, one encounters the unfathomable mystery of the origin of life. It is evident that in pursuing any branch of knowledge the seeker has opportunities of familiarizing himself with ideas contained in the phrases, 'invisible world,' 'infinity,' 'mystery,' and with facts that require application of all the powers of the imagination and of reason, to grasp which he exercises faith.

Most scientists having this mental training, in which acts of faith are demanded at every step, find it natural to apply this faith to their hypostasis of the spiritual world; they thus acquire belief in an inscrutable Divine Being, who exercises almighty wisdom and power in the guidance of the material universe, and who has made Himself known to humanity by revelation. To such persons it does not seem more difficult to believe in spiritual force and its influence on mankind, than to believe in the existence of energy and its effects on matter. Huxley, who certainly can not be accused of religious bias, is said to have

remarked: "The doctrine of the immortality of the soul is not so wonderful as that of the conservation of energy or of the indestructibility of matter."

The evidence of the existence of spirit is precisely analogous to the evidence for matter; matter, as we have seen, is revealed to us only as its phenomena, extension, weight, color, behavior when subjected to heat, etc., affect our senses; of its essence we know nothing; spirit, likewise, is revealed to our consciousness through its powers of thinking, feeling and willing, but of the essential spirit the finite mind knows nothing. "Matter," writes an American scientist, "is the thing perceived, spirit the thing perceiving, matter is the passive, spirit the active principle. Without a belief in spirit, therefore, not only can there be no religion, no virtue, but there can be no philosophy or science. * * * The very origin of our notion of force is the consciousness of our own mental energy, and this universal energy of Nature is an effluence of the Divine Being."

Faith, both in science and in religion, is belief based on suitable evidence from sources outside of personal experience, both are fruitful in different ways, the former affecting the intellect and the latter the heart of man; scientific faith bears fruit in the steamship and in the telegraph, Christian faith in works of mercy and charity and in a life of love shown toward mankind and to God; it is

> "The subtle chain
> That binds us to the Infinite."

On the other hand, some students of science, accustomed to exercise faith in their attempts to solve obscure problems in the material world, hesitate (and a few refuse) to extend this intellectual power to the spiritual universe; this is undoubtedly due to the operation of the will, for

> "A man along that road is led
> Which he himself desires to tread."

The supreme goal of the student of science was admirably conceived and expressed in a single sentence by the renowned Kepler, when he wrote nearly three centuries ago:

"The scientist's highest privilege is to know the mind and to think the thoughts of GOD!"

H. CARRINGTON BOLTON.

WASHINGTON, D. C.

THE SOCIETY FOR PLANT MORPHOLOGY AND PHYSIOLOGY.

THE Society met, together with the American Society of Naturalists and the Affiliated Societies, at Johns Hopkins Medical School, Baltimore, Md., December 27–28, 1900, under the presidency of Professor D. P. Penhallow. There was a large attendance of members, and the meeting was in all ways profitable and successful. The presidential address dealt with 'A Decade of North American Paleobotany'; it was published in this Journal for February 1st. The most important business of general interest was the presentation of the report of the Committee (Messrs. Farlow, MacDougal and von Schrenk) appointed to consider methods of securing improvements in reviews of current botanical literature. Copies of the report were distributed to members present, and have been sent to other botanists throughout the country. It shows a completely successful result of the Committee's work, and comments upon it will appear later in this Journal. A committee was also appointed (consisting of Messrs. Ganong, Lloyd and Atkinson), to take into consideration the formulation of a standard college entrance option in botany. On Saturday, December 29th, the members of the Society, with guests, made an excursion to Washington, where they were shown the work of the Department of Agriculture, and were received by the Honorable Secretary for Agriculture,

who made a brief informal address. Later they were entertained at luncheon by the botanists resident in Washington. The following new members were elected: M. A. Carleton, Department of Agriculture, Washington, D. C.; F. D. Chester, Delaware Agricultural College, Newark, Del.; E. B. Copeland, University of West Virginia, Morgantown, W. Va.; T. H. Kearney, Department of Agriculture, Washington, D. C.; J. W. Toumey, Yale Forest School, New Haven, Conn. Officers for the ensuing year were elected as follows: *President*, Erwin F. Smith; *Vice-Presidents*, F. C. Newcombe and L. M. Underwood; *Secretary*, W. F. Ganong. The following papers were presented, the abstracts of which in most cases have been furnished by the authors:

Notes upon Albinism in Sweet Corn: PROFESSOR BYRON D. HALSTED, Rutgers College.

Complete albinism has been found in a sweet corn cross between 'black Mexican' and 'Egyptian' after the second year. The tests show that the albinos come from the white, pink and purple grains in about equal numbers and in some instances fifteen per cent. are white plants. These albinos have the normal vigor and in every way adhere to the type, except in the lack of a capacity to produce chlorophyll. They begin to lag behind their green mates after two weeks and perish a fortnight later. In the dark they grow like the normal plants, except that no etiolin is produced. A large number of seeds, germinated under unfavorable conditions, were not influenced in the percentage of albinos, and it seems quite certain that the albinism is acquired before the tests were made. Some ears in the lot of crossed corn produced no white plants, while others show many, and it seems to be a fact that grains from overburdened plants, *e. g.*, where there are three large ears, are more apt to produce albinos than those from stalks with a single ear. The cross may have been such that the last act in the drama of perfect seed-production was not reached. Again, the close breeding of the crossed grains, all plants in the plot being of the same mother and with no pollen from other plots, may have had its effect in the manner mentioned.

A Disease of the Locust: DR. HERMANN VON SCHRENK, Shaw School of Botany.

A destructive disease of the black locust (*Robinia Pseudacacia*), due to *Polyporus rimosus*, was described. The fungus destroys the heart wood of this tree, leaving a soft, yellow mass. The fruiting organs form on the trunk and larger branches for many years, discharging their spores in the summer and fall. Attention was called to the fact that the mycelium grows only in the heart wood of living trees, and dies as soon as a tree is cut down. This is probably due to changed conditions of aëration, moisture and temperature. This fungus must be considered as a special class of saprophyte.

Observations on the Mosaic Disease of Tobacco: MR. ALBERT F. WOODS, Department of Agriculture.

The author presented the results of numerous experiments showing that the mosaic disease of tobacco may be artificially produced in the following ways: (1) By cutting plants back during any stage of active growth, thus removing most of the reserve organic foods and stimulating rapid growth of lateral buds in the absence of sufficient albuminoid reserve. This causes a remarkable increase in the activity of oxidizing enzymes. These enzymes inhibit the action of the translocation diastase of the cells, thus preventing the movement and assimilation of starch. When a plant once reaches this stage it seldom recovers, all new growth becoming diseased. He was able to produce the same disease in

the same way, in tomato, potato, petunia, phytolacca, violet and other plants. (2) The disease may be reduced by repotting or transplanting a plant in active growth, thus stimulating a rapid root development. New leaves that form at this time often come diseased. Leaves that form at the time of the development of the flowers also often come diseased, as do also rapidly developing suckers. The pathological changes are the same in these cases as when the disease is produced by cutting back. (3) The disease may be produced by injecting the sterile juice of diseased plants into the growing bud or by pouring it on the roots. Perioxidase obtained from healthy or diseased plants and injected into the bud or poured on the roots may also cause the disease. The author concludes as follows: "The evidence which I have collected, taken along with that obtained by other workers, especially Mayer and Beijerinck, is therefore very strongly in favor of the infectious nature of the trouble under certain conditions. The matter can not, however, be considered as settled. So far as the evidence at hand goes, it appears that in growing cells there is possibly a definite relation between active oxidizing power, through the medium of oxidizing enzymes, and the availability of reserve food to the growing cells. It appears that this balance between the oxidizing enzymes and the availability of reserve foods can be broken by removing, on the one hand, the supply of reserve foods, in any way during growth, in which case the enzyme content of the cell is increased from two to four times the normal activity. This removal of reserve food may be either the result of diversion to other parts of the plant or of direct removal, as in the case of cutting back or of sucking insects, and possibly also can be brought about by other conditions not at present understood. On the other hand, the most remarkable thing is that the introduction of the enzyme in question (perioxidase) sets up the same series of pathological changes as is brought about by the removal of reserve food, namely, the increase of the normal enzyme of the cell, and the decrease of availability of reserve foods. When this pathological condition is reached it is very difficult for the plant to correct the trouble. The perioxidase probably moves from one part of the plant to another, though how much of the general spread of the disease in the plant is due to such movement has not been determined. The evidence of the communicability of this disease is quite as strong, if not stronger, than that upon which rests the belief in the communicability of ordinary variegation through grafting on healthy plants. The two groups of diseases are at least very closely related and are probably simply different phases of the same malady. Possibly peach yellows and the California vine disease belong here also and are to be similarly explained. Die-back of the orange may also belong here.

The paper was illustrated by two colored-plates and four half-tones, and will be printed as a bulletin of the U. S. Department of Agriculture.

Report of the Committee appointed to consider Methods of securing Improvements in Reviews of Current Botanical Literature: Presented by the Chairman, Professor W. G. Farlow, Harvard University.

This report has already been referred to, and a further account of it will be found in a later number of this Journal.

The Cause of the Red-brown Color in certain Cyanophyceae: Dr. G. T. Moore, Dartmouth College.

The various theories which have attempted to explain the cause of the red-brown color in *Anabaena, Gloiotrichia, Oscillatoria* and other so-called 'blue-green algae,' were discussed. It was shown that this

color could not be due to sulphur granules, as has been supposed,—neither was it possible to demonstrate any definite coloring matter within the cell itself. Numerous experiments with *Oscillatoria prolifica*, Gorn., a plant particularly favorable for study, showed that the red color must be caused by the refraction due to the presence of large numbers of gas vacuoles, as suggested by Klehban. The effect of a large number of reagents, spectroscopical analysis and the examination of microtome sections, all strengthened this theory. As far as could be determined the enclosed gas seemed to be nitrogen. It would seem that the buoyancy common to so many Cyanophyceae, is particularly due to the presence of these vacuoles, for in material of the normal blue-green color the plants remained at the bottom of the dish, while those containing vacuoles and consequently of a red-brown appearance, always floated upon the surface.

Improved Methods for obtaining Pure Cultures of Fresh-water Algae: DR. G. T. MOORE, Dartmouth College.

The results of some methods for obtaining pure cultures of algae, by the modification of the nutrient medium, were shown. It was found that algae might be separated from contaminating forms by a very slight modification of the salts upon which they are grown. Luxuriant growths of Cyanophyceae were obtained upon a decoction of *Zamia*, with the addition of peptone and sugar. It required less than one-half the time for algae grown on this medium to nearly double the growth of those on mineral salt solutions. The possibility of using heat in separating blue-green algae from grass-green forms was also referred to.

A Second Preliminary Report on Plant Diseases in the United States due to Rhizoctonia: DR. BENJAMIN M. DUGGAR, Cornell University and MR. F. C. STEWART, New York Experiment Station.

This report presented notes upon the occurrence and destructiveness of American forms of *Rhizoctonia* observed by the authors. Since the first report (presented to this Society in 1898), the occurrence of *Rhizoctonia* on some entirely new hosts has been observed, and also upon other hosts new to America. As principal host plants among vegetables may be mentioned bean, sugar-beet, cabbage and cauliflower, carrot, celery, cotton, lettuce, potato, radish and rhubarb; and among flowers, asparagus, china aster, carnation, coreopsis, sweet william and violet; also about ten other less important hosts. In many cases the *Rhizoctonia* is truly parasitic and undoubtedly the cause of the disease in question, as has been abundantly proved by experiment; but in other cases inoculation experiments are yet lacking. Morphological studies and extensive inoculation experiments are in progress to determine more carefully the physiology of the forms and the limitations of species.

The Bacterial Diseases of Plants: DR. ERWIN F. SMITH, Department of Agriculture.

This consisted of a stereopticon lecture before a joint meeting of the Society for Plant Morphology and Physiology and the Society of American Bacteriologists. Three diseases were described, namely, the wilt of cucurbits due to *Bacillus tracheiphilus*, the brown rot of solanaceous plants due to *Bacillus solanacearum*, and the black rot of cruciferous plants due to *Pseudomonas campestris*. Fifty-eight slides made from the author's clear and beautiful photographs and photomicrographs were exhibited, showing symptoms, location of the bacteria in the tissues, etc. Many of these illustrations will be published in the near future in *Centralblatt für Bakteriologie*, 2te Abteilung.

Notes on the Life History of certain Uredineae: M. A. CARLETON, Department of Agriculture. (By invitation.)

Four species of rust fungi were investigated. In the case of *Uromyces euphorbiæ* Cooke & Peck, the well-known rust of *Euphorbia*, it was demonstrated by three separate series of experiments that the rust is able to propagate itself constantly through the germinating seed of its host, and therefore becomes in that way practically a perennial species. It is the only demonstrated example of this manner of propagation in the whole order of Uredineae. Actual cluster cups may be seen in the hulled seeds of *Euphorbia dentata*. Seedlings kept under bell jars become rusted three months from the date of planting, showing all stages of the rust, while seeds disinfected with mercuric chloride produce no rusted plants.

Culture experiments were also performed with the common sunflower rust, which showed that the *Puccinia* and *Æcidium* found on sunflower are stages of one and the same species. At the same time it is made probable that all the species of *Helianthus* affected bear the same rust and that there is no distinction of host forms. The peculiar, thick-walled, one-celled spores of *Puccinia vexans* Farl., have at last been successfully germinated after repeated failures, and it is now seen that these spores are neither properly uredospores nor teleutospores, but partake of the nature of both. They make up a distinct new spore form for this order of fungi, and may be called *amphispores*. True uredospores were also found and germinated. Other experiments and observations have shown that *Æcidium tuberculatum* Ell. & Kell. is commonly a perennial species in its perennial host *Callirrhoe involucrata*, producing spores able to germinate during the coldest winters.

Rheotropism of Roots: Professor Frederick C. Newcombe, University of Michigan.

The phenomenon of rheotropism is manifested by a curvature of the root when growing in streaming water. In all cases so far observed the response has been positive, *i. e.*, the root-tip curves against the stream. The present research has included 32 species of plants, of which 15 have shown themselves rheotropic and 17 insensitive. Nearly related plants behave similarly; but of two genera of the same family, one may respond to the current of water, and the other may be insensitive. Species differ greatly in degree of response. Members of the *Cruciferæ* are among the most sensitive plants found, their roots often attaining an angle of 90° from the vertical.

The velocity of current calling forth the best response lies between 100 cm. and 500 cm. per minute. A velocity of 2,000 cm. per minute will in most plants bring a mechanically negative curve, and the responses in currents less than 100 cm. per minute are weak and transitory. However, a velocity as low as one cm. per minute will bring a curvature in the majority of roots of the garden radish.

The latent period at the optimum temperature for growth is one hour or more.

The area which perceives the stimulus includes the apex of the root and the elongating zone.

Roots of mature plants as well as those of seedlings are responsive.

The author four years ago suggested that the stimulus might really be referred to the one-sided pressure of the water upon the root. Considerable evidence is now offered to confirm this view.

Thigmotropism of Roots: Professor Frederick C. Newcombe, University of Michigan.

Only two authors have claimed for ordinary roots the presence of sensitiveness to contact or pressure. Darwin believed he had found a negative response (a turning away), when the sloping side of the root apex touched a foreign body; and Sachs in a single and simple experiment found some

roots bending positively when a pin or a thin wooden rod was brought against the root 2 to 4 mm. back from the apex. Wiesner and others have shown Darwin to be mistaken, and the author of the paper here abstracted has repeated Sachs' tests many times without convincing results.

That roots are, however, responsive to pressure on the elongating zone can be shown by two kinds of experiments. Seedlings of buckwheat or radish are placed upright with their roots immersed in water, and a loop of very thin rice paper attached to a light pendulum is made to pull lightly on the elongating zone. Not more than half the roots bend, but all that do curve become concave on the side pressed by the paper. A better method is employed when gravitation is neutralized by revolving the seedlings in a vertical plane by the use of a klinostat. In this experiment the seedlings are supported in a damp chamber while their elongating zone rests lightly on a fixed glass rod. In sensitive roots, the tip of the root curves partially around the glass rod as growth goes on. These experiments show that some species respond and some do not respond to pressure. As far as the study has been carried, roots which are rheotropic are also thigmotropic. This agreement is strong evidence for the view that rheotropism is really thigmotropism. Neither rheotropism nor thigmotropism would seem to be of biological import to the plant. The response may be of the same class of phenomena as shown by tendrils when in contact with a solid object.

The Effect of Mechanical Shock on Longitudinal Growth of Plant Organs: DR. JAS. B. POLLOCK, University of Michigan.

The plant organs used were hyphæ of *Phycomyces*, hypocotyls of *Brassica*, *Raphanus*, *Helianthus*, *Lupinus*, and *Cucurbita*, the epicotyl of *Phaseolus*, and the leaf sheath and first leaves of *Avena* and *Triticum*.

Single shocks were given by pressure (*Phycomyces*) as by forcibly bending from side to side.

In *Phycomyces* there was a retardation after pressure, then a recovery in 5–30 minutes, usually in about 10 minutes, and the growth was then sometimes faster and sometimes slower than at first.

On bending, the larger plants first elongated considerably, were then retarded for a short time and recovered in 20–50 minutes, so they grew at a fairly constant rate, this rate being sometimes greater, sometimes less than at first.

Continuous shock was produced by several pieces of apparatus worked by electricity, water motor or clockwork, and was either a swaying from side to side or a jolting upon a board hinged at the middle.

The results were very decisive only in the case of *Cucurbita*, and showed a decided acceleration, due perhaps to the swaying from side to side. With all the other plants used the results were quite variable, but, taken as a whole, give evidence of acceleration as the result of not too vigorous swaying from side to side.

The Limits of Variation in Plants: DR. JOHN W. HARSHBERGER, University of Pennsylvania.

The study of the limits of variations in plants was undertaken as in part a contribution to the problem of species. It was stated, as a well-known fact, that more plants are produced than can survive, necessitating the destruction of many, and the survival of those that have fitted themselves by certain aptitudes to do so. As in part an answer to the evolutionary difficulty of small or initial variations, a careful statistical inquiry was made by comparative measurements of various plant parts. It was found, that the size and shape of leaves, the weight and size of fruits varied by mathematically ascertainable quantities. These

were determined for a number of plants and tabulated. It was discovered that in *Liriodendron tulipifera, Sanguinaria Canadensis, Ailanthus glandulosus* variations in the size and configuration of the leaves were in part due to the persistence of juvenile forms, to the arrested development of some leaves, and to their evolution and transformation to higher forms. The amount of these differences was ascertained, contrasted and tabulated. In conclusion, it was stated that these changes are in most cases due to two causes, viz., the internal hereditary impulse determining, as in *Ailanthus glandulosus*, the asymmetry of the lateral, paired, leaflets, and to the direct, environmental influence, fitting the leaf to utilize the space at its disposal, thus enabling it to present the largest amount of leaf surface to light action.

Critical Points in the Relation of Light to Plants: Professor D. T. MacDougal, New York Botanical Garden.

The following statements, upon the basis of accepted facts, may be made as to the influence of light upon plants:

1. Light exercises a direct chemical effect upon the substances of which protoplasm is composed.

2. It stimulates protoplasm to the formation of chlorophyll, although its action is not necessary to the process, and its direct chemical effect disintegrates this substance.

3. It constitutes a source of energy, which is absorbed by the chlorplasts.

4. Absence of light constitutes a specific stimulus, calling out the various reactions of etiolation.

5. Light acts as a directive or orienting stimulus to which the plant responds by locomotory or bending movements.

6. Different portions of the spectrum are operative in producing these separate effects.

If an examination is made of the facts upon which these generalizations rest, with reference to the current conceptions of *phototonus, paratonic influence* of light, *maximum, minimum* and *optimum*, it will be found that illumination is not necessary to the motility of protoplasm, and conversely that deprivation of light does not induce a condition of *rigor*, but sets up various pathological phenomena, among which is the breaking down of chlorophyll.

Light does not exert a paratonic or retarding effect upon growth. Its chemical action may hinder the accumulation of somatic material however. The altered development of plants in darkness is an adaptive response which has for its purpose the elevation of the chlorophyll screen and reproductive bodies.

Chemical, photosynthetic and phototropic maxima, minima and optima are so widely separated that *phototonus* as a term to designate the condition of a plant when acted upon by light of an optimum intensity, or of an intensity between the maxima and minima, is useless and untenable, as are also light optimum, maximum and minimum when applied in generality to the light relations of the plant.

Propagation of Lysimachia terrestris: Professor D. T. MacDougal, New York Botanical Garden.

The development of the secondary and tertiary branches of the stems of *Lysimachia terrestris* is arrested by conditions unfavorable to seed formation, and these branches assume the form of short cylindrical organs less than 1.5 cm. long without epidermal openings, and consisting of 3 to 5 internodes. The stele shows only protphloem and protoxylem. These bulbils fall to the ground and may survive under the cover of dead leaves to reproduce the plant in the next season. The bulbil completes its development as a rhizome and does not perish, as in most cases of bulbs and bulbils. Bul-

bils are quickly killed by desiccation and freezing temperatures.

Seedlings of Arisæma: PROFESSOR D. T. MACDOUGAL, New York Botanical Garden.

The seedlings of *Arisæma Dracontium* generally do not develop the plumule. The cotyledon pushes down into the soil carrying the hypocotyl, the base of which enlarges to form a bulb, in which is stored the reserve material withdrawn from the seed and not used. In a few instances, however, a single small leaf is developed; usually this does not take place until the second season of activity or the third season of existence of the seed. Similar saprophytism is exhibited by the seedlings of *Arum maculatum* which never develop the plumule until the second year of growth.

The Insular Flora of Mississippi and Louisiana: PROFESSOR FRANCIS E. LLOYD, Teachers College, and PROFESSOR S. M. TRACY, Biloxi, Miss.

The paper deals with the climate, physiography and the vegetation of the Mississippi Sound Islands and Delta, and is especially concerned with a comparison of the ecological conditions in this region and that recently studied by Kearney, namely, Ocracoke. The results show for the former a longer growing season, more favorable wind conditions and a greater amount of sunshine.

The islands of the Delta region are of three kinds, the sand islands, the muck-marsh islands and the mud-lumps.

These islands have a strand vegetation of which four formations are recognizable, viz., the beach, sand plain, dune and salt marsh formations.

The beach formation contains succulent annuals of a halophytic character such as *Suæda linearis*, *Salsola kali* and *Sesuvium portulacastrum*, and in its upper zone some tropical strand plants such as *Ipomœa pes-capræ*, *I. acetosæfolia* (two prostrate leaf-succulent morning-glories), and rarely *Canavalia obtusæfolia*. The back beach plants are chiefly grasses, of which *Panicum amarum*, common along the north Atlantic Coast, and *Uniola paniculata*, a more southern strand plant, are the leading elements.

The sand plain contains succulent perennials as well as annuals, of prostrate and cespitose habit. The most striking plants of the sand plain are *Iva imbricata* and *Serenoa serrulata*, a prostrate palmetto, both of which build a pedestal dune.

The dune formation has two leading associations. One of these is the thicket (Ilex-Myrica) association inhabiting small established dunes which support a plentiful herbaceous undergrowth. The larger dunes are inhabited by *Serenoa serrulata*, *Rhus copalina* and several grasses. These dunes may attain a height of twenty meters and in their leaward march may bury the trees in their path.

The salt-marsh associations of chief interest are those of the muck-marshes. Two such are to be seen, namely the *Batis-Salicornia* association composed of leaf and stem succulents, and the grass association of which *Spartina* (two species) is the leading type. On the muck-marsh is sometimes superposed a water-moved shell dune composed of shell fragments and supporting a vegetation of annual and perennial plants of less marked halophytic character.

Some Problems connected with Fertilization in Plants: Lecture by PROFESSOR G. F. ATKINSON, Cornell University. (Illustrated by stereopticon.)

Professor Atkinson discussed recent advances which have been made in the study of fertilization in plants and their significance, and pointed out the problems still awaiting solution.

The Morphology of the Fruit of Opuntia: PROFESSOR J. W. TOUMEY, Yale University. (By invitation.)

Primarily the function of fruits is seed production, secondarily protection of seeds and aid in their dissemination. The fruit of the *Opuntia* does not deviate from this general law; although, in many instances, it has developed special adaptations. Under their desert environments, with many species, the germination of seeds and development of seedlings are rarely attained, the dependence for reproduction being almost entirely upon vegetal dissemination. In *Opuntia fulgida* the fruit is mostly sterile, but is particularly adapted to aid in the dissemination of the tumid spine-covered terminal joints, as these joints become attached to animals that feed upon the spineless fruit and thus become scattered by them. In this special case the function of the fruit is no longer to produce seeds, but to entice animals to the plant that the fragile, terminal branches may adhere to them and become disseminated. As before stated, the fruit is frequently sterile. In some instances, however, we find clusters of spineless, short, proliferous joints which resemble the fruits externally, but are entirely without evidences of even an abortive ovary. These proliferous clusters of spineless stems, in the economy of the plant, serve the same purpose as the fruit clusters and without the necessity of floral development, which would be a useless waste of energy on the part of the plant.

Notes on Long Island Pine Barrens: Dr. Hermann von Schrenk, Shaw School of Botany.

Photographs were exhibited illustrating the manner in which young trees of *Pinus resinosa* form basal shoots after the tops have been killed by fire. Some trees do this four years in succession, showing an unusual vitality in the root system. The effect of repeated fires on the barrens was discussed, and it was pointed out that a gradual degeneration of the forest is very marked.

Suggestions for an Attempt to secure a Standard College Entrance Option in Botany: Professor W. F. Ganong, Smith College.

The author pointed out the advantage to any science of the interest taken in its teaching by experts and scientific societies. The increasing use of botany as a college entrance option is emphasizing the lack of differentiation and definiteness in the secondary teaching of the science, as well as the diversity of requirement through which a great burden is placed upon those preparatory schools which fit students for a number of colleges. A summary is given of the requirements made in this subject by leading colleges. The history of the efforts to secure the formulation of a widely acceptable standard preparatory course was traced, culminating in the 'Report of the Committee of the National Educational Association in 1899.' The reasons why the latter is not more widely adopted were traced, and suggestions made as to the characteristics of a course likely to be more generally accepted. It was recommended that a committee be appointed to take the subject into consideration, and to endeavor to secure the formulation and adoption of such a course. This committee was appointed, as already mentioned in the introduction to this article.

Further Notes on Spermatogenesis of Zamia: Dr. Herbert J. Webber, Department of Agriculture.

The mature pollen grain of *Zamia* was found to contain two well-marked prothallial cells, and besides these a dark, refractive slit could frequently be observed in the wall of the pollen grain, at the base of the other prothallial cells, indicating that the first prothallial cell cut off becomes oppressed and largely resorbed during the development of the pollen grain as in *Ginkgo*.

These cells the writer referred to as the first, second and third prothallial cells, in the order of their formation.

During the development of the pollen tube and prothallial apparatus in the nucellar tissue after pollination, the second prothallial cell crowds out into the third prothallial cell which meanwhile retains its original point of attachment and comes to surround the second prothallial cell like a root-cap. When the third prothallial cell divides to form the stalk cell and central cell (Körper cell, generative cell), the spindle is formed diagonally in the cell, the nucleus of the forming stalk cell being crowded to one side by the intruding second prothallial cell. When the stalk cell is cut off by the completion of the division, it appears nearly cylindrical and completely surrounds the second prothallial cell except at the base, where both cells retain their original attachment. This same structure and development have been found by the writer to occur in *Ginkgo* also, and while in *Ginkgo* the division of the third prothallial cell has not been observed, the writer thinks there can be no doubt that the development is the same as in *Zamia*. This interpretation, it should be added, is totally different from that described by Ikeno and Hirase as occurring in *Cycas* and *Ginkgo*, but neither of these investigators observed the division of the third prothallial cell.

During the development of the apical end of the pollen tube in the tissue of the nucellus, the vegetative nucleus passes into the tube and during the growth of the latter remains near its apex. When the proximal end of the tube (the pollen grain end) begins to grow down toward the archegonia, shortly preceding fecundation, the vegetative nucleus travels back through the entire length of the tube, two or three millimeters, and takes position in the proximal end of the tube near the central cell. This change of position suggests that the nucleus governs and directs growth, and changes its location in the cell in order to be nearest to the point of most active growth, a factor emphasized by Haberlandt in his 'Function und Lage des Zellkernes.'

Notes on the Spermatozoids of Ginkgo: ERNST A. BESSEY, Department of Agriculture. (By invitation.)

In Washington the spermatozoids of *Ginkgo* are developed between August 25th and September 10th, as extremes, the most favorable time for finding them being September 1st to 3d. They are developed in the night or early morning. They are about 105×75–$82\,\mu$ in size, with nucleus 71–75 μ. The nucleolus is 7.5 μ in diameter. The cilia are about 15 μ long. There are three turns in the spiral band which bears the cilia. The spermatozoid has no tail such as Hirase described, the latter's observation being probably on injured specimens, as Fujii has recently pointed out.

The ciliar motions are the regular tremulous motions of the cilia and also a series of waves passing from the apex to the base of the spiral. The body of the spermatozoid is very movable, especially the ciliferous portion, twisting, bending, elongating and contracting very remarkably. At the base of the cell, exactly opposite the apex of the spiral, there is a trembling motion apparently coincident with, and connected with the movement of the cilia. Its significance has not been determined.

Spherites and Sphere Crystals and their Relation to Plant Structures: DR. HENRY KRAEMER, Philadelphia College of Pharmacy.

On the basis of their physical properties the author has grouped the substances making up the contents and walls of plant cells into (1) the cell liquids or cell fluids; (2) sphere crystals; and (3) spherites. The cell liquids include the organized contents of the cell and a portion of the unorganized contents as cell sap. The sphere

crystals are spherical aggregates of crystals with sharp angular contours, which are made up of but one substance and include various calcium salts, alkaloids, glucosides, etc.

The spherites resemble somewhat the sphere crystals, but are distinguished from them by the fact that the molecule is complex and the individual crystals have either a somewhat rounded outline or are imbedded in colloidal substances in which the crystalline or crystalloidal character is more or less obscured and hence with difficulty discerned. These include inulin, starch and the principal substances entering into the composition of the cell wall. The spherites are further distinguished from the sphere crystals in that they are capable of taking up or holding certain coloring principals as safranin, gentian, violet, etc.

The mode of formation of spherites and sphere crystals appears to be the same whether observed in nature or as carried out artificially by crystallization of salts from solutions or by precipitation, and hence the conclusion is reached that there is a play of similar forces in their formation.

An examination of the crystal masses remaining in watch crystals after the spontaneous evaporation of various substances under varying conditions, shows not only the formation of crystals which resemble those produced in the plant cell, but other rather striking forms of combination which are very suggestive indeed. Indeed the arrangement of the crystals in such a watch crystal reminds one of the appearance of our woods, at this season of the year, when the absence of leaves permits the observance of the fundamental lines of development in shrubs and trees.

The Cardinal Principles of Morphology: Professor W. F. Ganong, Smith College.

Although in most of its phases botany is making remarkable advances in America, it is still in one respect very backward, namely, in the morphology of the higher plants. Not only is little research being carried on in this direction, but it is still treated, particularly in its teaching, in the old formal idealistic manner, with little of the modern realistic spirit which the research of the past quarter century has infused into it elsewhere. The characteristics of the two systems, which differ less in fact than in point of view, are contrasted, and the attempt made to reduce these characteristics to definite named principles. Of these principles the author recognizes seven, in five of which the two systems do not differ materially, but in the other two they differ greatly. These are, the principle of metamorphosis by transformation or alteration as contrasted with metamorphosis by differentiation, a principle which is fundamental with the modern school of morphologists of which Goebel is the leader, and the principle of the existence of degrees of morphological rank culminating in morphological independence to which any part may attain. On this principle any part may become a center of variation and modification, and hence a true morphological member, and the number of members is not limited to three or four for the higher plant, as generally taught by us, but is indefinite.

Relation of Water-plants to the Solid Substratum: R. H. Pond, Maryland Agricultural College. (By invitation.)

Many of our well known text-books contain the statement that the roots of water plants serve for attachment only ; that the function of absorption is unnecessary because transpiration is absent and the plant is bathed in a nutrient solution.

The evidence now at hand seems to require a modification of this statement. Six of our common and widely distributed

aquatic species have been investigated. The results in general are:

1. Plants rooted in soil exceed in vegetation and dry weight plants rooted in sand or merely suspended.

2. Plants rooted in sand or merely suspended contain starch, calcium and magnesium in excess, while they are lacking in nitrogen, potash and phosphoric acid.

3. Lithium nitrate is absorbed by the roots and conducted to the upper portions of the plant where it may be detected with the spectroscope.

4. A volumetric measurement of root absorption has been made.

The work which has yielded these results has been done by the author while a special assistant to the U. S. Commission of Fish and Fisheries.

Positive Geotropism in the Hypocotyl: PROFESSOR E. B. COPELAND, University of West Virginia. (By invitation.)

The curve by which the primary root is bent downward if it emerges from the seed in any other direction is usually executed in the hypocotyl. By decapitation experiments and by a careful study of the location of the curving region, with reference to the growing tip, it is shown that the stimulus causing this curve is received by the root tip. To distinguish between the parts played by the root tip and the hypocotyl Czapek's terminology is adopted, the latter being geotropic, the former, geoæsthetic. The positive geotropism of the cotyledon of the date and other plants, where it is the first part of the embryo to elongate actively, is explained in the same way; the stimulus is received by the root tip, and the response is executed in the elongating zone above it, which is here in the cotyledon.

The Toxic Action of certain Salts on Marine Algæ: DR. BENJAMIN M. DUGGAR, Cornell University.

Plasmolytic studies upon some marine algæ at the Naples Biological Station demonstrated that KNO_3 is too toxic to be used for such work. This led to a study of some of the common nutrient salts as toxic agents in comparsion with some salts of the heavy metals and with certain acids.

In general the results indicate that potassium salts are much more toxic than those of sodium and magnesium. All the algæ used were killed by an exposure of three days in $\frac{n}{25}$ K_2HPO_4 in sea water K_2SO_4, KNO_3, and KCl were also toxic in a slightly decreasing ratio. With the magnesium and sodium salts used, and for a similar period of time, no injury occurred at $\frac{n}{5}$. Salts of the heavy metals were much more toxic than for the fungi; and in general, the acids used were very slightly toxic at $\frac{n}{1000}$. With no salt tested was it possible to keep the plant alive for more than a few hours in a solution of that salt isotonic with sea water. *Griffithsia Schousberi*, *G. opuntioides*, *Pleonasporium coccinium*, and *Chætomopha* sp. were the algæ used.

Loss of Vigor in Corn from Inbreeding: DR. HERBERT J. WEBBER, Department of Agriculture.

In maize the loss of vigor caused by close inbreeding was found to be very marked. Seeds of Hickory King, a race grown commonly in the eastern States, produced by inbreeding with pollen of the same stalk, yielded the next year at the rate per hundred stalks of 46 ears, weighing $9\frac{1}{3}$ pounds. Seeds of the same race in every way comparable, but produced by crossing different seedlings, yielded under the same conditions at the rate per 100 stalks of 82 ears, weighing $27\frac{1}{2}$ pounds.

In attempting to fix hybrids of Hickory King ♀ × Cuzco or Peruvian Corn ♂, some ears were inbred with pollen from the

stalks bearing them, while others were pollinated with pollen from other hybrid seedlings of the same parentage. The hybrids of the second generation, where the seed was inbred with pollen from the same stalk, showed great loss of vigor, being small in stature and almost totally sterile; while those produced from seed which was inbred with pollen from a different seedling were much more vigorous and productive, seeming to have lost but little by this process of inbreeding.

Judging from these observations, it would seem that in fixing corn hybrids in practical plant-breeding it will be found desirable to cross different hybrid seedlings of the same parentage, which are found by careful observation to present the same characters, rather than inbreed a hybrid with its own pollen, as is somewhat generally directed by plant-breeders. It is of the utmost importance in plant-breeding that the best methods of fixing hybrids of various kinds of plants be determined, and further observations on this point with other plants are greatly needed.

W. F. Ganong,
Secretary.

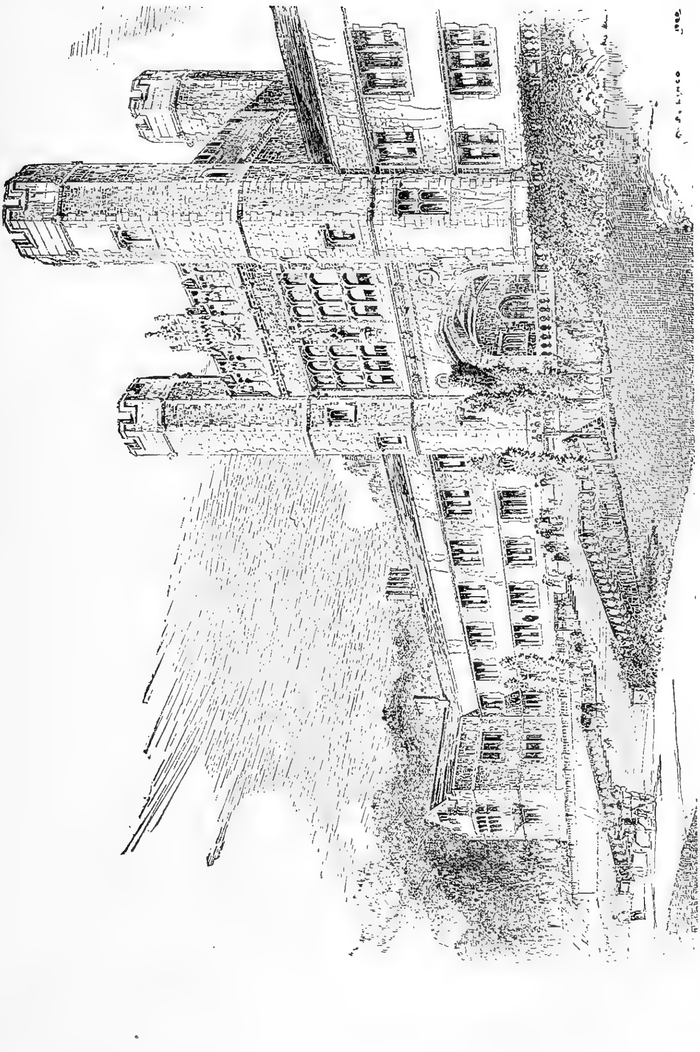
WASHINGTON UNIVERSITY.

The new grounds of Washington University are situated at the western boundary of the city just west of Forest Park. The distance from the Mississippi River is about six miles and from the business center of the city about five miles. The most direct approach from the city is along Lindell Avenue. The site covers 153 acres and cost $350,000. The eastern boundary of the ground is Skinker Road, from which the land rises rapidly westward for about 1,000 feet. About 1,200 feet from Skinker Road is placed the main building of the institution, to be called University Hall and to be devoted to the offices of administration and to those subjects which do not require a laboratory or a drawing room. This building forms the eastern side of the first quadrangle; the other buildings on this quadrangle are Busch Hall, to be devoted to chemistry, Cupples Hall No. 1, to be devoted to Civil Engineering and Architecture, and the Library which separates the first quadrangle from the second.

On the second quadrangle are also to be Cupples Hall No. 2, which is to be devoted to electrical and mechanical engineering, a building for physics, and sites for other buildings not yet planned. The first and second quadrangles are to be devoted exclusively to buildings for instruction. The other quadrangles are to be devoted to dormitory buildings. Those to the north of the Broad Walk are intended to be occupied by women students and those to the south of the Broad Walk by men students. The Broad Walk, something over a third of a mile long, leads to the gymnasium, near which is the athletic field, which will be excavated in the top of the hill in the form of an amphitheater. The architects, Messrs. Cope & Stewardson, of Philadelphia, have so arranged the quadrangles as to occupy the highest land of a long hill whose general direction is east and west.

Seven of the buildings shown on the general plan are to be constructed at once, and five of them are already under construction. The St. Louis, Kansas City and Colorado Railroad, running along the north line of the property at the bottom of the hill, makes it easy to bring in the supplies for the University. The power house, located beside the railroad track, will provide heat, light and power for all the buildings. The buildings generally will be two stories high on the quadrangles and three stories high on the opposite sides. The buildings to be erected immediately will cost about $700,000, and about $100,000 will be expended in the grading and planting of the grounds.

The style of architecture is what is called



University Hall, Washington University.

Tudor Gothic which appears so prominently in the buildings of the Universities of Oxford and Cambridge. The amount of cut stone in the buildings will be large ; the material used for this purpose comes from the Bedford quarries of Indiana. The field of the walls is to be of rubble masonry of red Missouri granite. It is expected that the five buildings now under way will be completed in about one year.

Besides these gifts, the University has recently received gifts for its endowment fund of three and a half million dollars, part available at once and part available after a few years.

W. S. CHAPLIN,
Chancellor.

THE BUSCH CHEMICAL LABORATORY.

THE new chemical laboratory of Washington University, the plans of which appear in this number of SCIENCE, is the generous gift of Mr. Adolphus Busch of St. Louis, who has given the University \$100,000, for its construction and equipment. The building is situated on the south side of the university quadrangle, and as the ground slopes away on this side, the new laboratory is two stories high on the north front and three stories on the south. Directly opposite on the quadrangle is the Cupples Hall No. 1 devoted to Civil Engineering and Architecture, while adjoining it on the east is the large and beautiful University Hall. The windows of the Busch laboratory command a beautiful view of the campus to the north and west, while to the south and east they overlook the wooded hills of Forets Park. The laboratory stands to-day as an enduring monument to the liberality of Mr. Busch.

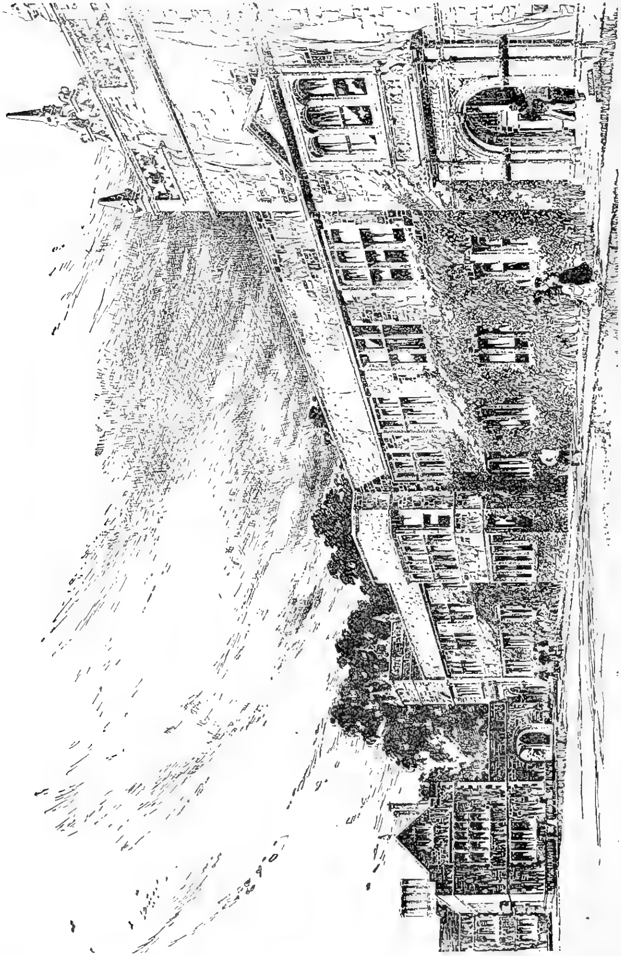
The architects of the building are Messrs. Cope and Stewardson of Philadelphia and St. Louis, who a few years ago designed the John Harrison Laboratory of Chemistry of the University of Pennsylvania. In planning this laboratory they have retained all of the desirable features of the Pennsylvania laboratory, they have avoided everything that experience has shown to be undesirable and have in a number of ways improved upon their earlier work.

The building is of Tudor Gothic design, the walls are of Missouri granite, the ornamental cut stone work of the windows and doors is of Bedford limestone. It is of fire-proof construction throughout. From the illustrations it will be seen that the building is long and narrow. The length is 291 feet and the width 60 feet. This plan was adopted in order that all the rooms may be well lighted, and since the main length of the building extends from east to west, a long north front with ample window space is secured for the main working laboratories.

Entering at the east front door, one finds immediately on the left the large lecture theater, a room 46 feet by 30 feet 10 inches. The rows of seats rise one above another, and there are places for 186 students. The front of the lecture room is half a flight lower than the rear. Immediately in the rear of the lecture theater and communicating with it is the preparation room. Here the lecture experiments are prepared and the apparatus and chemicals used in the lectures are stored.

Passing westward in the main corridor on the first floor, one finds on the right a large laboratory devoted to general chemistry. This room is 130 feet 6 inches by 18 feet. Here are working tables for the accommodation of 125 students. The new feature in this laboratory is that each working table is placed with one end against a window. On each side of the table are drawers and cupboards for four students. Each table, having a window at the end, is well lighted, and no student works further than twelve feet from a win-

dow. On the wall opposite the windows there is a continuous line of hoods extending from one end of the room to the other.

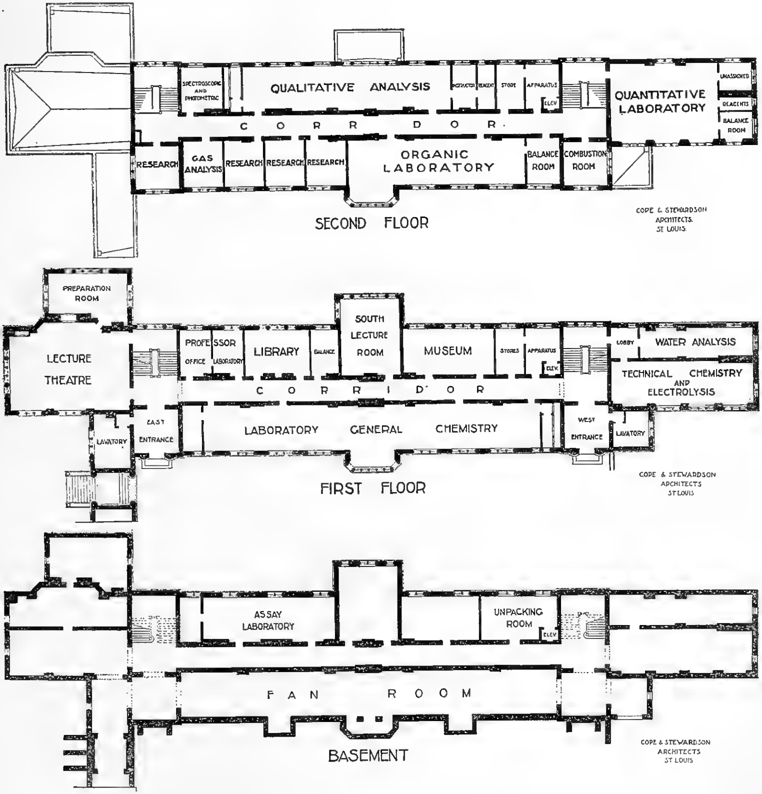


The Busch Chemical Laboratory.

At each end of this large laboratory there is a small room, one of these is used as a hydrogen sulphide room, the other as a storeroom for keeping the stock bottles of reagents.

On the south side of the corridor are the professor's office and private laboratory,

the library and balance room, a lecture room, 23 feet by 32 feet, seating 60 students, a museum and storerooms for apparatus and chemicals. At the west end of the building and half a flight lower there dows on the north and south sides. This is the laboratory for quantitative analysis, and communicating with it at the western end are smaller rooms for balances, reagents and a private laboratory for the in-



Ground Plan of Busch Chemical Laboratory.

are rooms for special kinds of chemical work, such as water analyses, electrolytic work and technical chemical operations.

Ascending the western stairway one-half flight, one reaches a large room, 41 feet 9 inches by 32 feet, lighted with large windows on the north and south sides. This is the laboratory for quantitative analysis, and communicating with it at the western end are smaller rooms for balances, reagents and a private laboratory for the in-

structor. On the main second floor there are two laboratories, one of these, with working tables for sixty students, is devoted to qualitative analysis, the other, with places for thirty students, is arranged for work in organic chemistry. As

in the large laboratory on the first floor, the tables have their ends against the windows and the hoods extend along the interior walls. On this floor there are also four smaller rooms for research work, a room for photometric and spectroscopic work, a balance room, a room for organic combustions and store rooms for apparatus and chemicals. These last are immediately over the store rooms on the first floor, and communicate with them and with the unpacking room in the basement by means of an elevator.

In the basement, besides the unpacking room, there are two large well lighted rooms fitted up with furnaces for work in assaying. There is also a room for the apparatus used in preparing distilled water.

In the rooms on the north side of the basement are located the ventilating fans. These are driven by electric motors. In the system of heating and ventilating adopted cold air from the outside is drawn in by the fans and is forced over steam radiators and into the rooms. The warm air enters the rooms near the ceiling and the outlet flues have their openings near the floor. A separate system of fans, also driven by electricity, is placed immediately under the roof. These are connected with the hoods and with the hydrogen sulphide room, and they have been so arranged that they can be made to draw air from all the hoods or they can be made to draw simultaneously from the hoods of any one laboratory.

Edward H. Keiser.

SCIENTIFIC BOOKS.

Ueber die Natur der Centrosomen. By Theodor Boveri. Zellenstudien, Heft 4. Fischer, Jena. 1901. Pp. 220, 8 plates, 3 text-figures.

Probably the most remarkable series of cytological papers yet published by a single author are the 'Cell-Studies' of Theodor Boveri, which have placed before students of cellular biology not only a wealth of original discoveries, but also a model of critical analysis and lucid exposition that has hardly been surpassed. They form to-day a fine example of the value of intensive work in this field, for although they have extended over a period of nearly fifteen years they have been mainly devoted to the examination of but two objects, namely, the eggs of *Ascaris* and of the sea urchin; yet few works have accomplished more for the advancement of the general subject.

The first three parts, which appeared successively in 1887, 1888 and 1890, were inspired by the epoch-making res arches of Van Beneden on the eggs of *Ascaris*, and the first two were entirely devoted to the same object. The first cleared away the confusion of the earlier work regarding the formation of the polar bodies and laid the basis for most of the subsequent work on the reduction of the chromosomes, a subject which was thrown into especial prominence through the theoretical essays of Weismann. The second was a masterly study of the phenomena of fertilization and cleavage, with a full development of the hypotheses of the individuality of the chromosomes and of fibrillar contractility in mitosis, which exerted a far-reaching influence on all subsequent work in this field. The third placed upon a broad comparative basis the epoch-making discoveries of himself and Van Beneden on the equivalence of the paternal and maternal chromosomes in fertilization ('Van Beneden's Law'). The fourth, which appears eleven years after the third, deals with the nature and function of the centrosome, which has become one of the most difficult and perplexing problems of cytology. Students of cellular biology have eagerly awaited a critical discussion by Boveri of the later and in many respects conflicting aspects of this subject, in which he was one of the ablest pioneers. The present work contains a detailed study of the centrosomes in the segmenting eggs of *Echinus* and *Ascaris*, a valuable critique of technical methods, and a critical examination of the literature, with chapters on the structure and division of the centrosome in general, its relation to cell-division, its origin and physiological activity, and related questions.

All these matters are treated in the lucid and attractive style characteristic of the author, and the work easily takes its place as a worthy companion to its predecessors.

The portion of the work that will be read with greatest interest is that which deals with the vexed question as to whether the centrosome is a permanent cell-organ, comparable with the nucleus in point of morphological persistence. The independent discovery by Van Beneden and Boveri in 1887, that the centrosome in the *Ascaris* egg is such an organ, since extended to many other cases, was at first hailed as the most important step taken since the establishment of genetic continuity in the case of the nucleus. That a like principle applies to the centrosome, as was first stated by Van Beneden and Boveri, has been widely accepted by cytologists, but of late years a marked reaction against this view has taken place, a considerable number of competent observers having been led to conclude that centrosomes may form *de novo*, as well as by the division of preexisting centrosomes. While recognizing that the centrosome theory has been in some directions pushed too far, Boveri regards the present reaction as a backward step. Nevertheless, in the course of a highly interesting discussion, he makes a large concession to the advocates of formation *de novo*, though his general theory is developed with the utmost ingenuity so as to save the principle of genetic continuity for which he has always contended. He sharply distinguishes between a protoplasmic (cytoplasmic) and a nuclear origin of centrosomes. While formation of centrosomes *de novo* in the protoplasm is denied, such an origin is admitted in case of the nucleus, though with qualifications that involve only a modification and not the abandonment of his original theory.

The strongest evidence in favor of the cytoplasmic formation of centrosomes *de novo* is afforded by the observation of the American observers, Lillie, Mead and Morgan; but all arguments based on this evidence are regarded as 'in high degree vulnerable.' The multiple asters observed in the eggs of *Chætopterus*, *Arbacia* and other animals are believed by Boveri to be 'almost certainly' of two kinds, the one (polar asters, cleavage-asters) being true asters arising through the activity of the egg centrosome or its derivatives, the other being 'pseudospheres' of different nature from the former and containing no true centrosomes. All arguments based on the apparent disappearance and reappearance of the centrosomes in the cytoplasm during fertilization (as described for instance, by Lillie and MacFarland) are regarded as having little weight, in view of the impossibility of distinguishing the centrosome amid other granules when not surrounded by astral rays. On the positive side the persistence of the centrosome in *Ascaris* is once more demonstrated, step by step, throughout the first cleavage, and the same phenomenon is for the first time fully demonstrated in the egg of the sea urchin (*Echinus*) which, as Boveri emphasizes, is one of the most difficult of objects. These cases are illustrated by a large number of new and very convincing figures.

When Boveri turns to the nuclear origin of centrosomes he takes a different ground, basing his conclusions on the absence of centrosomes in the higher plants, on the phenomena of division in the Protozoa and on the experimental evidence brought forward especially by Hertwig and Ziegler. This interesting discusson is based primarily on the fact that in Infusoria and some other Protozoa a spindle is formed from the achromatic substance of the elongated nucleus, the bipolarity of the division figure being determined by the nucleus without the appearance of individualized centrosomes; and with this is compared the formation of the polar spindle in the eggs of *Ascaris*. To such a spindle the new term 'netrum' is applied (νῆτρον, spindle), and its mode of origin is assumed to be a primitive mode of spindle-formation to which all other types may be referred. The accumulation of substance at the poles of such a spindle to form 'pole-plates,' as occurs in some Protozoa, represents an incipient centrosome-formation, with which is compared the peculiar mode of division of the centrosome in *Diaulula* as described by MacFarland. In the latter case the centrosome is extra-nuclear, but its mode of division closely resembles the phenomena observed in Infusoria, the mother-centrosome elongating to form bodily the spindle from the ends of which are differentiated the daughter-

centrosomes. This case gives the transition to the usual types (*Ascaris*, cleavage, etc.) where the extra-nuclear centrosome divides bodily.

Boveri is thus led to regard the centrosome of the higher types as equivalent to the intranuclear material from which the 'netrum' of the lower types (Infusoria) arises, and he characterizes the nucleus of the latter as a 'centronucleus'—a view which is nearly identical with that of Richard Hertwig. In the higher types in general, individualized and permanent centrosomes have been differentiated, and as it were emancipated, from the primitive 'cenronucleus,' and as a rule lie outside the nucleus in the cytoplasm; but the nucleus has in some cases retained the power to give rise, upon occasion, to a karyokinetic spindle (as occurs in the polar spindles of *Ascaris*), or even to produce new centrosomes. This, Boveri believes, is the case with the egg-nucleus in echinoderms, and he would thus explain the division figures formed as a result of chemical stimulus. In normal fertilization, on the other hand, the centrosome-producing power of the egg-nucleus remains latent, since the spermatozoon imports an active individualized centrosome. How far the nuclei of higher forms in general have remained 'centronuclei' and still possess the power of forming centrosomes, how far they have lost this power, remains to be determined; but Boveri does not consider it probable that such a mode of centrosome-formation is wide spread. It is worth pointing out that Boveri regards as not improbable the view of Calkins that phylogenetically the primitive form of nucleus (centronucleus) may have arisen through the union in one body of a cytocentrum and other elements (chromatin) originally scattered through the general cell substance.

It is evident from the foregoing that the original centrosome theory of Van Beneden and Boveri, as commonly understood, has thus undergone a considerable modification, which will very likely be regarded by some readers as a virtual abandonment of that theory. Such is not, however, Boveri's own view. "Strictly speaking the cases in question do not involve a new formation. For even though the centrosome may not preexist as an individualized structure, it does not arise as something really new * * * but only by the final transformation of a preexisting cytocentrum" (p. 193).* If, however, we accept the widely held view that the achromatic nuclear substance is closely related to the cytoplasm, the step does not seem very great from the formation of 'individualized' centrosomes *de novo* out of the achromatic nuclear material to such a formation in the cytoplasm. Boveri's denial of such cytoplasmic centrosome-formation rests upon a series of assumptions, some of which are opposed by the recent discovery that Morgan's 'artificial astrospheres' may multiply by division, even in enucleated egg-fragments. He has nevertheless entrenched the centrosome theory in a strong position, from which it can only be dislodged by a stronger attack than has yet been made upon it.

Other valuable discussions deal with the relation of centriole and centrosome, and of centrosome and sphere, and with the physiological activities and cyclical changes of the centrosome. Without attempting to review these *in extenso* it may be pointed out that Boveri holds fast to the view that the centrosome passes through a regular cycle of changes, during one part of which it is a body of considerable size within which lies a smaller 'centriole.' He repudiates some of the interpretations that have been placed by other writers upon his own earlier observations, and identifies his 'centrosome' with Van Beneden's 'corpuscule central,' and not with the latter author's 'medullary zone' of the sphere. He overturns Kostanecki's and Siedlecki's contention that the size of the centrosome depends merely on the degree of extraction of the hæmatoxylin or other dye, by the highly important observation that when at its greatest size the centrosome in *Ascaris* is clearly visible not only in unstained material but also *in the living object.* He believes that the so-called pluricorpuscular centrosome, such as he himself and others earlier described in echinoderms, is an artifact; but his observations justify some severe strictures that are passed on the scepticism of such writers as Fischer, who have more than hinted that the centrosome itself is an artifact. Fischer's valu-

* For a related though not identical interpretation see Wilson, 'The Cell,' pp. 111, 215.

able experiments, with those of Bütschli, Hardy and others, have shown how much caution is necessary in the interpretation of the coagulated material observed in sections; but they have produced in some minds a pessimism regarding the morphological investigation of the cell that is without justification. The cyclical changes observed in sections of fixed material are not a matter of chance, but form a highly significant connected series, and many of them have been fully confined by comparison with the living material. The experiments in question have provided us with a valuable critique of our methods, but have not destroyed their value. Even though we may not agree with all the conclusions set forth in the present paper, we must regard it as weighing heavily on the side of the view that the cell possesses a definite and complex morphological organization that passes through perfectly ordered cyclical changes, and of which our cytological methods give us not indeed a photographic image, but still a definite record. EDMUND B. WILSON.

Elements of Mineralogy, Crystallography and Blowpipe Analysis. By ALFRED J. MOSES and CHARLES L. PARSONS. New York, D. Van Nostrand Co. 1900.

The edition of the book before us is in plan essentially like the former edition of 1895. Many parts have, however, been re-written and considerable additions are to be noticed in text and illustration.

The part devoted to crystallography has undergone complete revision, and in its treatment of the subject conforms to the prevailing classification. Over one hundred figures, for the most part excellent, have been added and we are pleased to note a new chapter treating entirely of twin crystals. The chapters on blowpipe analyses treat of the apparatus used in, and the operations of, blowpipe analyses. A summary of blowpipe tests is also given with a short scheme for qualitative blowpipe analysis.

The descriptive mineralogy opens with chapters treating of the various characters of minerals, that on optical characters being intended as introductory to a subsequent study of minerals in thin sections under the microscope. In the part describing the individual minerals we find them grouped according to the economic classification, viz., iron minerals together, copper minerals together, etc. Before each group a brief discussion is made of the uses of the particular metal in hand, the minerals from which it is obtained and the metallurgical processes involved in its production. We think this an excellent feature of the book. The silicates do not yield to such a classification and are grouped according to the usual chemical classification. While the descriptive part as a whole and in many of its details seems to us excellent and worthy of commendation, we can not but express our regret that it should be marred by so many poor illustrations. The crystal drawings are excellent, but with few exceptions the other illustrations are not what they should be. It is doubtless difficult to represent the characteristic appearance of a mineral on paper and unless great pains is taken in this regard it were better for both books and mineralogy not to attempt such illustration.

In describing the crystallization of the minerals we notice that the real angle between the crystal faces are given instead of the supplementary angle as is customary. As the latter angles are the ones most convenient for use in calculation it would seem desirable to have had them given.

The book is concluded by a series of tables designed for the rapid determination of the common minerals. C. H. W.

A Text-Book of Important Minerals and Rocks. By S. E. TILLMAN. New York, John Wiley and Sons; London, Chapman & Hall. 1900.

Professor Tillman has prepared this book with the idea of furnishing the general student of mineralogy with a convenient and serviceable book, condensed in form, yet sufficiently complete in descriptive matter to equip the student with a good general knowledge of the subject.

The opening chapter consists of a very brief outline of the crystallographic character of minerals. The second treats of other physical characters and of the chemical properties of minerals. With the latter is included a brief description of blowpipe and chemical tests. That four pages should be deemed sufficient for

the treatment of a subject so very important is rather astonishing, and it is the deficiency in this regard that will we fear detract from the general usefulness of the work. The main part of the book contains the descriptions of the individual mineral species, of which some seventy-five are described, and their occurrence and uses commented on. A series of tables for the determination of the minerals, chiefly by means of their physical characters, are included in the descriptive part and is designed to supplement the latter. Part II. furnishes a brief description and classification of the more common rocks. C. H. W.

Lehrbuch der anorganischen Chemie. Von Professor Dr. H. Erdmann, in Halle. Zweite Auflage, mit 287 Abbildungen, einer Rechentafel und sechs farbigen Tafeln. Braunschweig, Druck und Verlag von Friedrich Vieweg und Sohn. 1900.

To quote from the author's preface. "First of all a text-book of chemistry should give reliable data concerning the properties and reactions of substances; here were gaps to be filled, for our larger manuals generally take without criticism the frequently contradictory statements and figures of different authors. The most accurate data, however, remain lifeless matter for reader and student unless the book explains the occurrence of substances on a geological basis, gives due attention to their therapeutic and toxic properties, and due recognition of their importance for the common weal by a consideration of their varied application, and by statistics of production and price; nor should the historical aspect of the subject be neglected."

Through certain improvements in this edition "somewhat more space could be devoted to those theories which have sprung up on the boundary space between physics and chemistry. Yet their views should never occupy the main place in the presentation of chemistry. He who leads the student into our science by a by-path instead of stimulating him to *pure chemical thought*, does in verity make chemistry a 'science of inferior worth'" (Ostwald).

"As Clemens Winkler aptly says, 'physical chemistry in no sense covers the same field as inorganic chemistry, for the latter, far from being a closed branch of science, offers countless problems which must be solved by quite other methods than those furnished by the theory of ions.'"

The quotations indicate the character of the book. It is a masterpiece of descriptive chemistry, a book written for riper German university students. If a translation is made it will doubtless be harmfully introduced into our colleges, possibly into high schools. As there is fortunately no translation as yet, the use of the book will be limited to teachers and older students reading German, and to them it will be a benefit and a pleasure.

As introduction, the author in seventy-five pages discusses weight and measure, heat, theories of gases, Avogadros law, laws of chemical changes, etc. In short, he has brought together what is generally scattered throughout the book. If this were a book for beginners this method would be open to adverse criticism. For older students the reviewer believes it to be the better arrangement, especially when the treatment is as good as here. The author tacitly assumes that the reader is prepared by previous study to follow him without diffuse explanations.

The next division covers the non-metals in 400 pages, the last division the metals in 320 pages. Erdmann divides the non-metals as follows: *Chief gases*, oxygen, hydrogen, nitrogen. *Noble gases*, helium, neon, argon, krypton, zenon. *Air. Sulphur group*, sulphur, selenium. *Halogens*, fluorine, chlorine, bromine, iodine. *Phosphorous group*, phosphorous, arsenic, antimony. *Carbon group*, boron, carbon, silicium, germanium.

It is evident from this division that the author does not utilize the periodic system as a means of instruction; indeed he only devotes three pages at the close of the book to the system, his treatment coinciding with that of Ostwald's 'Grundlinien der anorganischen Chemie' in this respect, but in no other. This shelving of the periodic system is to be regretted; it does not accord with the influence which this system exerted and still exerts in the chemical thought and chemical work of the last thirty years and of the present.

At the close of each chapter is a beautifully

illustrated section headed 'Technique and Experiments'; these sections are very pleasing. The apparatus is of the most modern type, many experiments are new.

The author had Professor Ramsay's cooperation in rewriting the chapter on noble gases for this edition. The chapter includes full illustrated descriptions of the methods for obtaining argon and helium, and colored tables of the spectra of all the noble gases, showing the three spectras of argon—the blue, the red and the green. Another interesting chapter is that devoted to flame, illumination, photometry, burners, furnaces, fuel gases, fuels and heat values. In this, as indeed in the whole book, we find the newest methods and the latest statistical results. Striking examples of this are shown in the references to persulphuric acid and to radium; in the first instance the work of Baeyer and Villiger on 'Caro's Reagent' in the *Berichte* of June 7th is utilized for the book which appeared in October; in the latter instance we find in the chapter on barium a brief discussion of radio activity, radium and polonium and of the work of Becquerel, of the Curie's and of Lengyel.

Of more vital importance to the student are the methods of formation of substances and their use in modern technical chemistry, which are not found in any other text-book. For example, recently published books state that hydrochloric acid is obtained technically only as a by-product in the Leblanc process. Erdmann says that while in England one-half million tons of salt are used yearly for Leblanc soda, in other countries this process has only 'historical interest.' Hydrochloric acid, he says, is now made in Germany either as a by-product in the Glauber salt industry from salt and sulphuric acid, or by decomposing magnesium chloride with superheated steam. We find that magnesium chloride is obtained from Strassfurt Carnallite as by-product in crystallizing potassium chloride from Carnallite solution or as a by-product in the manufacture of Glauber salt by action of a solution of Strassfurt Kieserite on salt at low temperatures, 8,000 tons Glauber salt being made yearly by the latter method.

The theoretical side of the book is also well developed. Physical chemical theories are, it is true, but little utilized. The author explains the theory of ions briefly under the head of acids, and refers to this and other theories from time to time throughout the book, devoting seven pages at the end to a condensed discussion of the laws of electro-chemistry and of electrolytic dissociation; that is all. But if we examine Erdmann's treatment of any class of compounds in detail we find that more space is given to the theoretical side—as we have hitherto been accustomed to define 'theory'—than by Ostwald, despite the demand of the latter author that a text-book of chemistry shall devote all its space to 'pure chemistry.'

A comparison is justified by the decided stand both authors take. Both volumes are alike in size of page and type, Ostwald having 795 pages and Erdmann 757. The reviewer has chosen at random the oxygen and hydrogen compounds of nitrogen for the purposes of comparison. Ostwald devotes 36 pages to the subject; about one-half of this space is devoted to physical chemical considerations of great interest; the other half is descriptive chemistry in the narrowest sense, no reference being made to any modern work on structure. Erdmann gives 58 pages, of which 14 are given to illustrated experiment and technique; the remaining 44 pages give fact, theory and statistics; he opens the subject with 5 pages devoted to a study of the constitution of the compounds, relations of the different hydroxyl-acids, etc. Six pages follow on the formation, decomposition and properties of nitric acid, a full but carefully condensed statement. Ostwald gives 1½ pages to nitric acid, namely, composition HNO_3, saltpeter, Chili saltpeter, decomposition of Chili saltpeter by sulphuric acid in two stages, and a few words on the properties of nitric acid. In short, no more than is contained in an average school chemistry. Erdmann gives 4½ pages to hydrazine and hydrazoic acid; Ostwald, 1 page. Erdmann gives 2 to hyponitrous acid, explaining the stereoisomeric forms, which are ignored by Ostwald in the 15 lines given by him.

In a recent review of Ostwald's book it is said, "Every chemist should own a copy of this book and should conscientiously study it."

The present reviewer subscribes heartily to these words and intends no belittling of this brilliant book, but the fact remains that so much space in it has been required for the applications of physical-chemical theory, that much of what we have hitherto considered higher inorganic chemistry has been crowded out, theory as well as fact, and that Erdmann's book supplies those facts and those theories which are lacking in Ostwald's. Every chemist should own and study both books.

EDWARD RENOUF.

NOTES.

Copies of the 'Descriptive Catalogue of Government Publications of the United States from September 5, 1774, to March 4, 1881, compiled, by order of Congress, by B. Perley Poore, Clerk of Printing Records, are now for sale for $1.90. Remittance should be by money order payable to W. H. Collins, Chief Clerk, Government Printing Office, Washington, D. C.

THE work on the 'Mammals of Egypt,' left unfinished by the recent death of Dr. John Anderson, will be completed under the supervision of Mrs. Anderson.

UNDER the title 'First on the Antarctic Continent' Mr. Borchgrevink, the commander of the recent Antarctic expedition, has now completed the account of his voyage in the *Southern Cross* and of the adventures and incidents in the land near the South Pole. The volume will be published very shortly by George Newnes (Limited).

PROFESSOR WILBUR C. KNIGHT has published a large-sized block-line geological map of Wyoming in Bulletin 45 of the Wyoming Experiment Station, accompanying 'A Preliminary Report on the Artesian Basins of Wyoming.'

D. K. KEILHACK has issued, through the Gebrüder Borntraeger of Berlin, the fourth yearly edition of his Taschenbuch für Geologen, Palæontologen und Mineralogen.

SOCIETIES AND ACADEMIES.

GEOLOGICAL SOCIETY OF WASHINGTON.

AT the 109th meeting, held at the Cosmos Club, January 23, 1901, the following papers were presented:

Shell Bluff, Georgia, one of Lyell's Original Localities: T. WAYLAND VAUGHAN.

This locality is in Burke county, Georgia, on the Savannah River, about 20 miles in a straight line below Augusta, and about 100 miles above Savannah. It was examined by Sir Charles Lyell during his first visit to the United States and was first brought into prominence by him. Subsequently Conrad visited and studied the bluff, and considering it paleontologically peculiar, gave the name Shell Bluff Group to the beds there exposed, correlating them with the base of the bluff at Vicksburg, Miss., and placing them in the columnar section immediately beneath the Jackson. Later several other geologists, including Loughridge and Professor W. B. Clark, visited the locality. Because of the prolonged discussion as to the precise position of the Shell Bluff section in the Eocene series, Mr. Vaughan visited the locality during December, 1900, and made a considerable collection of fossils. All the face of the bluff, something over 70 feet, except the uppermost 10 feet, contains a fauna identical in essential species with the Lisbon beds of Alabama, the Wautubbee beds of Mississippi, and the Texan and Louisianan Lower Claiborne of Harris and Vaughan. The uppermost layers contain almost exclusively *Ostrea Georgiana* Conrad, no fossils that could be used as positive stratigraphic indices being found, but it is most probable that this portion of the section also belongs to the same horizon. Compared with the section at Claiborne, Alabama, the section of Shell Bluff can be correlated with the Lisbon, the second horizon beneath the Claiborne sands proper, *i. e.*, it is below the *Ostrea settonformics* bed which immediately underlies the Claiborne sands.

A few of the species are: *Turbinalia pharetra* Lea, *Endopachys maclurii* (Lea), *Mesalia obruta* (Conrad), *Venericardia planicosta* Lam., *Venericardia alticostata* (Conrad), *Corbula oniscus* Conrad, *Pteropsis lapidosa* (Conrad). Approximately forty species were collected.

Trias in Northeastern Oregon: WALDEMAR LINDGREN.

As a preliminary, the occurrences of marine Trias in the western part of North America

were reviewed. It was shown that a gap existed between the known localities in northern Nevada and California on one hand, and those of British Columbia on the other. This gap has partly been bridged by the discovery of an extensive series of marine Trias in northeastern Oregon. No Trias has previously been found in this State.

The result of a reconnoissance during the past field season has shown that the larger part of the Blue Mountains of Oregon are made up of older rocks of probably Carboniferous age. In the Eagle Creek Mountains, however, which form a circular mountain group in the extreme northeastern corner of Oregon, surrounded on nearly all sides by Columbia River lava, the marine Trias was found very strongly developed, although the fossils thus far obtained do not afford paleontological subdivisions. The fossils, though scant, unquestionably indicate a Triassic age. They consist, besides pentacrinus stems and fragments of echinoids and ammonites, of various specifically indeterminable Halobias and Danonellas. The series consists of a great thickness, probably several thousand feet of shales and limestones. Associated and interbedded with these are vast masses of tuffs and various old lavas. The limestone is very prominently developed and its weathering gives rise to peaks and cliffs of Alpine character.

The same series was found well represented in the Snake River canyon on the boundary of Idaho and Oregon. Here, however, the volcanic material predominates, the sedimentary rocks appearing as intercalated masses. Halobias were again found in this series. It appears that these Triassic rocks continue with a northeasterly strike into Idaho across the Seven Devils and the lower Salmon River Canyon, until at some point in the vicinity of the Clear Water River, they give place to intrusive granites and older schists.

A Comparison of the Ouachita and Arbuckle Mountain Sections, Indian Territory: J. A. TAFF.

The Ouchita mountain range extends from the vicinity of Little Rock, Arkansas, to the Missouri, Kansas and Texas Railway, near Atoka, in Indian Territory. The hard sandstone and novaculite formations make ridges rising from 1,000 feet at the end of the range, to nearly 2,000 feet in the central part. The high ridges have strikingly level crests which probably represent a Cretaceous plain. The softer rocks are generally worn down to heights between 600 and 1,000 feet above the sea.

The Arbuckle range, with the exception of a central igneous peak, contrasts strongly with the Ouachita range in physiographic aspects. It is strictly a plateau, only partially dissected and but little below the original Cretaceous base level. It rises gradually to about 1,350 feet on the west, from the Cretaceous contact having an average elevation of 750 feet, on the east and southeast. The gap between the Ouachita and Arbuckle uplifts is about 20 miles wide and is occupied by slightly disturbed coal measures and Cretaceous rocks.

The lowest rocks in the section of the Ouachita range are Lower Silurian sediments in the heart of the uplift near the Tertiary border southwest of Little Rock. Above these are the Lower Silurian novaculites, 1,200 feet thick, which were the highest Silurian strata recognized by L. S. Griswold, of the Arkansas Geological Survey. In Indian Territory above the novaculites are about 5,000 feet of shale. These are in turn succeeded by about 5,000 feet of sandstone. Above these sandstones comes limestone of Ordovician age. Lower Helderberg cherts and limestone, Mississippian shales and coal measures, complete the section above the Ordovician.

The section of the rocks in the Arbuckle mountain uplift from the Lower Helderberg upward is a repetition of the Ouachita mountain section upward from the same terrane, but is not nearly so thick. Below the lower Helderberg is a mass of Ordovician limestone with shale and sandstone of minor importance, reaching a total thickness of more than 6,500 feet. These cannot be compared lithologically with the known Ordovician in the Ouachita mountain uplift. The limestones rest uncomformably upon a mass of older granites with a variable intervening bed of arkose and conglomerate.

The structure of the Ouachita range is typically Appalachian. The rocks for the most part have been sharply folded and very extensively overthrust. The structure of the eastern

half of the Arbuckle uplift consists of relatively wide shallow folds. The axial portions of the synclines have been dropped down by opposite normal faults. In some instances the vertical displacements amount to many thousand feet. The softer and thinner formations, from the upper Ordovician to the coal measures, which occupy the downthrown blocks, were crumpled into narrow folds prior to the faulting.

F. L. RANSOME,
DAVID WHITE,
Secretaries.

SECTION OF BIOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

THE regular monthly meeting for January was held on the 14th, Professor C. L. Bristol presiding. Dr. H. E. Crampton was elected Secretary, in place of Professor F. E. Lloyd, resigned.

The following program was offered:

(1) 'A New Species of *Phoronis*': H. B. TORREY.

(2) 'Characters and Relationships of the Belodont Reptiles': J. H. MCGREGOR.

(3) 'Notes on *Chrysoma paucifloscuulosa*'; 'On the Occurrence of Nectaries in *Pteris aquilina*': F. E. LLOYD.

Mr. Torrey described a new species of *Phoronis*, the first that has been collected upon the western coast of America. It is intermediate in its characters between the European and eastern American species, and those found in Australia and the Philippines. In size it agrees with *P. Buskii.* The lophophore, though spirally coiled—thus differing from that of the European species—is less complex than that of *P. Buskii*, and the tentacles are fewer in number (200). The longitudinal muscles are stouter than those of *P. Buskii*, agreeing more nearly with the condition in *P. architecta* of the east coast. The new species agrees with this latter species in habit, in the possession of a longitudinal ciliated ridge in the digestive tract, and in the possible separation of the sexes.

Dr. McGregor presented the results of a recent study of the Belodonts, a group of fossil reptiles occurring in the Triassic of Germany and North America. The Belodonts have usually been regarded as ancestral crocodiles, though many students of the group have admitted possible affinities with Rhynchocephalia and Dinosauria. The material used in the present study, chiefly from the genera *Mystriosuchus* and *Rhytinodon*, yielded some parts new to science, *e. g.*, the atlas and clavicle. The presence of two cervical intercentra and a large clavicle tends to ally the group more closely to the Rhynchocephalia. The hyoid apparatus was found to be suspended from the skull as in Hatteria; and there is strong evidence that the carpals (and probably also the tarsals) remained cartilaginous throughout life. Some doubt was expressed regarding the Belodont ancestry of the crocodiles, though it was admitted that the Belodonts stand near the crocodilian stem. The suggestion was made that the Belodonts may belong on or very close to the line of descent of the Ichthyosauria, occupying a position midway between some Permian land-living Rhynchocephalian and the marine Ichthyosauria of the Jurassic. In support of this theory, many structures of the Belodonts were shown to be such as one would expect to find in an ancestor of the Ichthyosauria, *e. g.*, position of the nares, elongated premaxillary, bicipital ribs, form of the shoulder-girdle, etc. Some other structures, apparently incompatible with this view, were shown to be in reality not inconsistent with it.

In a discussion of Dr. McGregor's paper, Professor Osborn emphasized the importance of the Belodonts, and the conflicting nature of the opinions regarding them. Huxley placed them near the crocodiles, as evidenced by the choice of the name *Parasuchia* for the group. The paleontologists of the Stuttgart school relate them to Dinosauria. Dr. McGregor is the first to bring out the idea of their relationship to the Ichthyosauria; and, based as it is upon many new characters described for the first time, the theory is of great interest and importance.

Professor Lloyd stated that the chief point of interest in *Chrysoma paucifloscuulosa*, a sub tropical marine form, is in the structure of the leaves. The surface of these is sculptured in the form of a mosaic. This appearance is caused by deep and regularly-arranged involutions of the epidermis. At the bottom of each sulcus are to be found flagellated and glandular hairs, such as have been described by Vesque for

the Compositæ. Transverse sections show that each element of the mosaic contains chlorenchyma, which, though packed densely around the edges, forms in the middle a large air-chamber, suggesting in appearance the air-chambers of certain Hepaticæ. The leaf, a bifacial one, is maintained in a vertical position.

In a second paper, Professor Lloyd drew attention to the occurrence, in *Pteris aquilina*, of nectaries near the bases of the pinnæ. The activity of these glands reaches a maximum during the development of the frond in spring and early summer, at which time large drops of syrupy nectar exude from the openings, which are modified stomata. The object of the speaker was to call the attention of teachers of general biology to the presence, in a much-used laboratory type, of organs which, though discovered by Francis Darwin in 1877, were generally overlooked.

In discussion of Professor Lloyd's first paper, Professor Britton remarked that the author's results were of value as throwing light upon the vexed question of the relationship of *Chrysoma* to the golden-rods (*Solidago*). The two groups were probably distinct. It was also recalled that the late Dr. Gregory had worked extensively upon this problem, but her full results had never been published.

HENRY E. CRAMPTON,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of the Academy of Science of St. Louis of January 21, 1901, twenty-seven persons present, the following subjects were presented:

Rev. M. S. Brennan read a short sketch of the progress of astronomy in the United States, in which the material equipment and the discoveries made in that science in this country during the past century were passed in review.

A paper by Professor T. G. Poats, entitled 'Isogonic Projection,' was presented in abstract.

Professor F. E. Nipher showed by means of the lantern a series of negatives printed by contact from a lantern slide or positive picture, by the light of a 300 candle incandescent lamp. The unit of exposure adopted was one lamp-meter-second. The exposures varied from 0.0054 to 4,800. All were developed in the dark room with hydrochinon, those above 0.1 exposure having in the bath one drop of saturated hypo to the ounce of bath. The plate having an exposure of 0.1 seemed to be normally exposed. An exposure 210 gave a negative showing some fogging, but a print from it by ordinary methods gave a very satisfactory result. With longer exposures, the plate began to reverse, locally. With an exposure of 3,600, which was an exposure of one hour at a distance of one meter from a 300-candle lamp, half of the plate still showed as a negative. The shadow on the gown of a figure in the landscape showed white as a negative, and the part of the gown in sunshine showed white as a positive. The penumbra between light and shadow was darker. All the details were sharp, but lights and shadows were somewhat incongruous. With an exposure of 4,800 the details had not yet all reversed, but the greater part of the plate had become a positive.

The greatest exposure giving a negative which would yield an acceptable print was 210, which was 39,000 times the least exposure which would give a good negative. All exposures of 210 and over gave complete positives when the plates were developed 1.41 meter from a 16-candle lamp, or in stronger light. As good a picture as has been obtained had an exposure of 4,800, and was developed within half a meter of a 300-candle lamp. A fair picture had even been obtained from a two-hour exposure to direct sunlight with a Cramer 'Crown' plate. This plate was developed in a perfectly dark room.

It was stated that hypo in the developing bath did not affect the zero condition, or change the character as regards positive and negative. When no hypo is used, the plate fogs so quickly that the picture is invisible, before it has time to fully develop. After fixing, the thin shadowy picture showing on the fogged plate has the same local positive and negative characters that are shown on the clearly defined picture of the same exposure, when developed in the hypo-hydrochinon bath.

The greatest exposures giving good results that have been measured with reasonable accuracy were about 900,000 times as great as the

least exposure giving a good negative in the dark-room. This factor can certainly be trebled. A plate having any intermediate exposure can be developed either as a good positive in the light, or as a good negative in the dark-room.

It was stated that the best results with plates near the zero condition had been reached with a rather strong bath, with two drops of saturated hypo to the ounce of bath.

Three persons were elected to active membership.

WILLIAM TRELEASE,
Recording Secretary.

SCIENCE CLUB OF THE UNIVERSITY OF WISCONSIN.

THE January meeting of the Club was held on the evening of the 24th inst., President Birge in the chair. Professor J. M. Coulter, of the University of Chicago, delivered his address on 'The Teaching of Science' (substantially as published in this JOURNAL, Vol. XII., p. 281). At the close the president related an incident from his own early experience to show how completely scientific education was misunderstood by the classicists, and he expressed the opinion that the quality of science teaching in the universities is not so poor as Professor Coulter would have us believe. The president extended the very evident thanks of the audience to the speaker for his address.

E. R. MAURER,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE SIDGWICK MEMORIAL.

TO THE EDITOR OF SCIENCE: I have been asked to act in America for the English committee on a memorial to the late Professor Henry Sidgwick. Other Americans are probably acting also, but of this I do not know. A meeting in the interests of such a memorial was recently held at Cambridge, and an influential committee was appointed. The memorial will probably take the form of an endowed scholarship at Cambridge, though other projects are also before the committee. Seeing the services Sidgwick rendered to education—notably woman's education—and the very large use made of his books in American universities, it is hoped that a considerable sum will be raised in this country. Contributions, to be forwarded through me, may be sent direct to Princeton, New Jersey.

J. MARK BALDWIN.

SHORTER ARTICLES.

RADIO-ACTIVE MINERALS.

IN searching for radio-active substances with one of Professor Rood's new electrometers, an instrument particularly well adapted to the purpose, several minerals not hitherto noted were found to be radio-active. Professor Rood suggested that I should try columbite, and gave me some specimens. The electrometer immediately shows that the air in the neighborhood of the mineral is ionized, and later photographic tests confirm the radio-activity of columbite. A chemical analysis of the specimens has not yet been made, but according to Dana, columbite does not contain uranium or thorium.

Specimens of erbium oxide and niobium oxide, from the museum of the chemical department, also show with the electrometer a slight ionizing effect. Further investigations are being made.

GEO. B. PEGRAM.

PHYSICAL LABORATORY OF COLUMBIA UNIVERSITY, January 26, 1901.

THE MUSICAL BOW IN CALIFORNIA.

IN view of the present discussion in regard to the existence of the musical bow in America, and of its independent development on this continent, the occurrence (quite rare at present, however,) of a form of this instrument among the Maidu Indians of Northern California appears worthy of a brief note.

The bow as used by the Maidu is a simple bow of cedar, some 2½ feet in length, at present strung with wire, but formerly with a fine sinew cord. In playing the instrument it is held in the left hand (the hand grasping the center of the bow, thumb inside and palm facing forward), the bow extending horizontally to the left. The right-hand end of the bow is placed in the open mouth, and the bow string tapped rapidly with a small flexible twig held in the right hand. By varying the size of the resonance chamber (the mouth) with the aid of the tongue, and by opening or closing the mouth to a greater or

less extent, notes are produced as in a Jew's harp. The tones are, however, very faint, and are audible only at a short distance.

The use of this bow, known as 'kāwotöne panda,' is restricted to the medicine-men or shamans, and other persons are rarely allowed to see and never allowed to touch the instrument. The sacredness of this bow, the fact that it is used by the medicine-men only in communicating with and praying to the 'kukini' or spirits, and that its manufacture is accompanied by ceremonial observances, including the rubbing of the bow with human blood—all seem to point to the bow as being of native origin. The limited contact of these Indians with the negro, and the place held by the instrument in the religious life of the people, here as well as elsewhere in America, would seem to militate against the view that the musical bow is on this continent the result of acculturation.

Roland B. Dixon.

CURRENT NOTES ON PHYSIOGRAPHY.

THE YOSEMITE VALLEY.

A careful study of 'the Pleistocene Geology of the south central Sierra Nevada with especial reference to the origin of the Yosemite valley,' by H. W. Turner (*Proc. Cal. Acad. Sci.*, 3d ser., Geology, i, 1900, 261–321, 8 pl.) is of much interest, but still leaves this interesting problem without definite solution. The suggestion that the valley is a *graben* is discarded, yet direct proof or disproof of this view can be gained only when identifiable structures are found in the rocks of the valley floor and of the uplands, as has been done in the case of the Rhine *graben*. It is concluded that 'the canyons of the Sierra Nevada, like most other canyons the world over, were formed in the main by river erosion'; but it is suggested that after a rather extended glaciation of the Sierra highlands, narrow and deep canyons were cut in an interglacial epoch, and that ice streams of a second glacial epoch 'greatly modified the new-cut canyons of the interglacial epoch, and gave them, within the glaciated area, substantially their present form.' The contrast between the broad U-shaped section of the Yosemite and the sharp V-shape of the Merced canyon farther west seems to favor this view. Moraines are found on the valley floor at six points, the westernmost being where the open valley ends and the V-canyon of the Merced begins; it is pointed out that the size of the moraines would be greater if their bases were not generally buried in river sands and silts.

Gannett, commenting on Turner's article, forcibly maintains the glacial origin of the Yosemite, appealing especially to its hanging lateral valleys in support of his opinion (*Geogr. Mag.*, XII., 1901, 86–87).

PATAGONIA.

The geographical results of the Princeton expeditions to Patagonia are presented by Hatcher in most interesting form. ('Some geographic features of southern Patagonia, with a discussion of their origin,' *Nat. Geogr. Mag.*, xi, 1900, 41–55.) The eastern coast shows a line of sea cliffs, from 300 to 500 feet high, seldom broken except at river mouths where the few harbors are found. The strata in the cliffs are nearly horizontal, but by following them for long distances two marine formations separated by a continental formation are discovered, all being covered by 20 or 30 feet of unstratified boulders and clays, the great shingle formation, of glacial and aqueous origin. Vast plains stretch inland from the coast, subarid, bearing thin grass and scattered bushes; guanacos and rheas are found here in abundance. The plains are broken by escarpments, often several hundred feet high, trending north and south, and interpreted as sea cliffs formed during the latest emergence of the region. Recent lavas cover considerable areas in the central interior, forming scoriaceous plains of large extent, here and there dissected by canyons. Indeed, all these features are broken by the valleys of rivers coming from the back country. One of these valleys, that of San Julian, has at present no stream; its waters having been captured by a northern tributary of the Santa Cruz, 100 miles in from the coast. Numerous depressions holding small salt lakes are interpreted as remnants of an ancient valley system, now masked by deposits formed during the last submergence of the region. The district pied mont to the Andes is sheeted with morainic

drift, the most fertile part of the plains; water is here plenty in small lakes. The peculiar drainage system of the Andean region is explained chiefly by the Pliocene depression and elevation of a previously dissected mountain range. Glacial erosion is not especially considered as contributing to the present topography. W. M. Davis.

ZOOLOGICAL NOTES.

During the past year, L. Camerano has published (in *Atti della R. Accademia delle Scienze di Torino*, Vol. XXXV., and *Arch. Ital. de Biol*, Vol. XXXIII., fasc. 2) papers on the 'somatic coefficient.' These are based on a plea made by Andres that ichthyologists and others express the proportion of parts of the body not in relation to any other convenient organ, as is often done, but rather in thousandths of the total body length. Thus, if x is the proportion to be expressed, l is the observed dimension, and L is the total length of the body, in millimeters, then, $x = \frac{1,000}{L} l$. The factor $\frac{10,000}{L}$ is the somatic coefficient and is constant for all organs of the body. Camerano makes the suggestion that the number 360, being readily divisible by more integers, is preferable to 1,000 and he publishes a convenient table of values of $\frac{360}{L}$ for every quarter unit from 1 to 360. It is to be hoped, however, that those who express the dimension of organs in multiples of the somatic coefficient will not fail to give also the absolute lengths of the organs, as these are of no less importance. C. B. D.

In describing to the Zoological Society of London, on January 15th, the collection of fishes brought home from Lakes Tanganyika and Kivu by the Tanganyika exploring expedition, under the leadership of Mr. J. E. S. Moore, Mr. G. A. Boulenger pointed out that the study of this important collection did not modify the conclusions embodied in his first report published in 1898. The exploration of Lake Kivu had thrown no light on the origin of the Tanganyikan fauna; the smaller lake proved to be very thinly populated with fishes, which all belonged to widely distributed genera, the species showing a mixture of Nile and Tanganyika elements, with two that might prove to be endemic. The list of the fishes from the two lakes comprised 91 species, 74 of which had been named by the author. The collection now described consisted of examples of 50 species, 26 of which were new to science, 2 being made the types of additional genera of the family *Cichlidæ*.

A BILL ESTABLISHING A NATIONAL OBSERVATORY.

We are now able to publish the text of the bill introduced into the Senate by Mr. Morgan on January 21st. The provisions seem to be all that could be asked, and it is to be hoped that men of science will unite in urging its passage. Personal letters to members of Congress and resolutions adopted by societies and institutions and forwarded to the Committee on Naval Affairs are the most effective way to advocate the measure. The bill is intended 'to organize the National Observatory of the United States' and reads as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the United States Naval Observatory shall hereafter be known as the National Observatory of the United States, and shall be governed by a Director thereof, who shall report directly to, and be under the supervision of, the Secretary of the Navy.

Section 2, That the Director of the National Observatory shall be an eminent astronomer, appointed by the President, by and with the advice and consent of the Senate, at a salary of five thousand dollars per annum, and shall be selected from the astronomers of the National Academy of Sciences unless, in the judgment of the President, an American astronomer of higher scientific and executive qualifications shall be found.

Section 3, That the Secretary of the Navy may detail for duty as astronomers at the National Observatory such professors of mathematics and other officers of the Navy as he shall deem necessary in the interests of the public service; but on and after the

passage of this Act no appointments shall be made of such professors unless required for service at the Naval Academy.

SECTION 4, That there shall be a Board of Visitors of the National Observatory, to consist of one Senator, one member of the House of Representatives, and three astronomers of eminence, to be selected by the Secretary of the Navy. The Board of Visitors shall make an annual visitation, or more frequent visitations, of the Observatory, advise with the Director thereof as to the scientific work to be prosecuted, and report to the Secretary of the Navy on the work and needs of the Observatory on or before the first day of November in each year. The members of the said Board may receive an allowance not exceeding ten dollars per day each during their actual presence in the City of Washington while engaged on the duty of the Board and their necessary traveling expenses; but no officer of the Government appointed on the Board shall receive any additional compensation for such duty above his actual expenses.

THE REORGANIZATION OF THE DEPARTMENT OF AGRICULTURE.

THE Agricultural Appropriation Bill, as presented to the Committee of the Whole of the House of Representatives, contained provisions for the reorganization of the Department of Agriculture, which we much regret were afterwards withdrawn, owing to the point of order being raised that new legislation had been attached to an appropriation bill. It is well-known that the salaries in the Department are too small, and that the Government is constantly losing the services of its trained scientific men. Thus Dr. Loew received a salary of $1,800 in the Department of Agriculture, and has now accepted a position under the Japanese Government at a salary of $7,000. The plan proposed by the Committee on Agriculture would have created four new bureaus, the chiefs of which would have received a salary of $3,500 a year, and who would have been the chiefs of divisions who now receive $2,500 a year, and the salaries of the other scientific experts would have been increased by sums varying from $200 to $500 each. The total increase in salaries would have been $26,000. In recommending this plan the Secretary of Agriculture, the Hon. James Wilson, wrote to the Chairman of the Committee on Agriculture, the Hon. J. W. Wadsworth, on January 15th, as follows:

Having gone over with care the proposed plan for the reorganization of the Department of Agriculture, I am pleased to state that it has my entire approval. The grouping together of scientists in kindred lines of work will enable us to bring to bear on each subject considered and on each undertaking before it is begun the experience of all the division chiefs interested, avoiding duplication of work, which quite frequently occurs under our present divisional system, and in that regard will enable us to economize.

The salaries as proposed are not in excess of what is paid to scientists doing like work in educational and experiment station institutions throughout the country, and are, in fact, much below the salaries paid by many institutions in the land that seek men of the greatest experience and highest attainments. The work now being carried on by this Department and the amount of money being expended by Congress justify the employment of the foremost scientists in every line.

We are not able to retain our best men at the present time. Other countries, as well as home institutions, take them away from us by offering more money than our statutory salaries. If it were possible for this Department to go to the country, through the Civil Service Commission, and get scientists well informed regarding the work we are doing for the farmers, the loss of a man now and again would not be so serious.

But this Department is compelled, in many of its divisions, to educate its own men. When they leave us, on account of getting better pay elsewhere, our work in some cases stops until new men can be trained.

I therefore sincerely hope that you will succeed in having the proposed rearrangement enacted into law. It will do much to facilitate our work, and I believe will in the end be economical.

It is to be hoped that the reorganization of the Department, approved by the Secretary of Agriculture and the House Committee on Agriculture, will be introduced as a special bill. Scientific men at Washington can not well advocate a measure that increases their salaries, and there is consequently every reason for those interested in science and not connected with the Government service to use all efforts to secure the introduction and passage of a measure that is essential for efficiency and economy.

SCIENTIFIC NOTES AND NEWS.

At a meeting of the Prussian Academy of Sciences, held on January 24th, the announcement was made that the Helmholtz Medal had been conferred upon Sir George Gabriel Stokes, of Cambridge University. The medal has hitherto been conferred only on Professor Virchow and Lord Kelvin.

At a meeting of the Council of the Astronomical and Astrophysical Society of America, held in New York, on January 29th, at which all members of the Council save one were present, the previous action by which Denver was designated as the next place of meeting for the Society was reconsidered, and by unanimous vote the Council determined to hold no meeting during the summer of 1901. In lieu of the customary summer meeting of the Society, a winter meeting will be held in the City of Washington during the next Christmas holidays, and Professors Newcomb and Brown were appointed a local committee to arrange the details of such meeting. The Committee upon Legislation affecting astronomical interests made through its chairman a report of progress, and was continued. Professor W. W. Campbell, director of the Lick Observatory, was elected a member of the Council in place of the late Professor James E. Keeler.

Professor R. W. Wood, of the University of Wisconsin, has decided not to accept the invitation of the director of the U. S. Naval Observatory to go to Sumatra as a member of the eclipse expedition, but he has fitted up a polarizing spectroscope to test the method, recently described by him in Science, of photographing the Fraunhofer lines in the spectrum of the corona, by placing a Nicol prism in front of the slit of the instrument in such a position as to transmit the polarized light reflected by the coronal particles. Dr. Norman E. Gilbert, of the Johns Hopkins University, will operate the instrument, the observations being both visual and photographic. The visual work will be confined to the few moments at second and third contact, when the flash spectrum is seen.

The Reale Accademia dei Lincei of Rome has elected to membership the Duke of the Abruzzi.

Dr. M. Cantor, honorary professor of mathematics in the University of Heidelberg, has been elected a corresponding member of the St. Petersburg Academy of Sciences.

Mr. Evelyn B. Baldwin returned to New York on February 3rd, after having arranged, while abroad, for two vessels for his North Polar Expedition.

Professor Francis E. Lloyd, of Teachers College, Columbia University, has gone abroad on a leave of absence, and will spend the next eight months at Bonn.

Dr. William R. Brooks, director of the Smith Observatory and professor of astronomy in Hobart College, Geneva, N. Y., recently delivered two illustrated lectures in the opera house of that city on 'The Wonders of the Sun and the late Eclipse.' The stereopticon views included a large number of photographs of the eclipse in its partial phases, made at the Smith Observatory, and others taken at different points along the total belt.

A bronze bas-relief of the late Professor M. S. Newberry, the eminent geologist, has been presented to Columbia University by his children.

A bust of Dr. Horace Green, who died in 1866, was presented to the New York Academy of Medicine on February 8th by Mrs. Green and George Walton Green. Dr. D. B. St. John Roosa made a commemorative address.

Miles Rock, whose death in Guatemala was noted in Science of February 8th, was from 1883 to 1898 chief engineer and president of the Guatemala Commission to locate the

boundary between that country and Mexico. His services to Guatemala were so important that he was given an imposing public funeral at the expense of the government, the ceremonies taking place at the National School of Engineers and being attended by President Cabrera and his cabinet.

PROFESSOR MAX VON PETTENKOFER, of the University of Munich, the eminent authority on hygiene and bacteriology, has committed suicide at Munich. He was eighty-three years of age.

MR. R. D. LACOE, well known among geologists and paleontologists for his great aid in the advancement of the sciences of paleobotany and pale-entomology, died at his home in West Pittston, Pa., on the fifth of February.

PROFESSOR JOHN POTTER MARSHALL, until his retirement in 1899, professor of geology and mineralogy in Tufts College, died at his home at Tufts College on February 4th in his seventy-seventh year. He graduated from Yale College in 1844 and was one of the founders of Tufts College, where at first he had charge of all the scientific work, including mathematics, and where he held a professorship continuously for forty-five years.

PROFESSOR EDWARD ELBRIDGE SALISBURY, for sixty years professor of Arabic and Sanscrit at Yale University, died at New Haven on February 5th.

DR. WALTER MYERS, a member of the expedition of the Liverpool School of Tropical Medicine to Brazil, has died from yellow fever while engaged in investigating the disease. Dr. Myers was a graduate of the University of Cambridge and was only twenty-nine years of age.

THE death is announced in his seventieth year of Dr. Bernhardt Danckelmann, for the last 35 years director of the Prussian Royal Academy of Forestry at Eberswalde. He was one of the first to advocate the training of foresters in special colleges, and was the author of important works on forestry.

THE London *Times* announces the death, at Bois de Colombes at the age of 74, of M. Gramme, the eminent Belgian electrician. Brought up as a carpenter, he attended scientific lectures at Liège, where he showed a talent for machinery, and then went to Paris to a manufactory of light house electric lamps. He next worked under Ruhmkorff and Disderi. In 1867 and 1872 he patented electric batteries and the dynamo. For the latter he received 20,000 f. from the French Government and the Volta prize of 20,000 f. from the Academy of Sciences.

THE will of the late Charles F. Emerson gives $100,000 to the town of Castine, Maine, for a library.

WE learn from the *Electrical World* that the private electro-chemical laboratory of Mr. C. P. Steinmetz has been destroyed by fire, which probably had its origin in a coal stove. A considerable part of the apparatus was saved, but a number of interesting investigations being carried out in the laboratory are indefinitely delayed.

THE National Academy of Sciences has made a grant of $500 to the University of California from the Draper fund for the promotion of scientific research, the money to be used in the construction of a first-class one-prism spectrograph for the Lick Observatory.

LORD RANFURLY, Governor of New Zealand, has secured a fine collection of birds for the British Museum, including the *Merganser Australis*, which is almost extinct, and specimens of two species new to science.

THE collection of birds and mammals formed by the late Geo. A. Boardman, of Calais, Me., will be removed to Fredericton, N. B., and will occupy a conspicuous place in one of the Government buildings.

UNIVERSITY AND EDUCATIONAL NEWS.

MESSRS. WILLIAM KEYSER, William Wyman and Francis W. Jenks have offered to give the Johns Hopkins University a new site, on condition that $1,000,000 be collected for the University. The proposed site is some hundred and seventy acres in extent, and is valued at $750,000. It is in the northern part of the city of Baltimore and is well adapted for the purposes of the University.

IT will be remembered that at the recent election an amendment to the constitution of the State of California was adopted, permitting the

Legislature to exempt portions of the property of Leland Stanford Junior University from taxation. A bill has now been passed to the third reading in the Assembly by a vote of 47 to 15, exempting from taxation the real estate occupied by the University and bonds held by it.

THE higher court has sustained the decision upholding the validity of the will of Colonel Joseph M. Bennett which, it will be remembered, left a large estate to the University of Pennsylvania.

BY the will of Daniel A. Buckley, late publisher of the Cambridge (Mass.) *News*, an estate, valued at between $50,000 and $60,000, is bequeathed to the city of Cambridge to be used for the education at Harvard of such graduates of non-sectarian schools as a committee may deem worthy.

IT appears that the school fund of the State of Minnesota has been increased by the discovery of iron ore. Ten million tons have been sold in position for $2,500,000, and it is said that at least 50,000,000 tons can be disposed of in the same way. The State school fund now amounts to $12,500,000, invested in bonds and securities, and the school and university lands are valued at more than $20,000,000.

THE Rensselaer Polytechnic Institute at Troy, N. Y., has in operation a new electrical laboratory containing sixteen machines, generators and transformers, together with a full equipment for practical tests. The laboratory for the testing of materials of engineering has been increased by the addition of one 300,000 pound testing machine and one 100,000 pound testing machine; and a 10,000 pound wire testing machine. There is also a new cement testing laboratory fully equipped for the most approved modern tests.

THE ladies of the Temple Emanu-El in San Francisco, one of the largest Jewish congregations on the Pacific Coast, have founded two graduate fellowships in Semitic languages in the University of California. They have pledged themselves to pay to the University in cash, within two years, the full amount of the endowment, $15,000. Some years ago the ladies of the congregation presented to the university a Semitic library of over three thousand volumes. Jacob Voorsanger, D.D., rabbi of the Temple Emanu-El, has for some years served without remuneration as professor of Semitic languages and literature in the university.

LORD GEORGE HAMILTON has refused to grant the inquiry asked for by the dismissed members of the teaching staff at the Royal Indian Engineering College at Coopers Hill, but it is understood that leading English scientific men will continue the agitation for such an inquiry.

JOHN HUDSON PECK has resigned the presidency of the Rensselaer Polytechnic Institute, and a committee of the Board of Trustees is considering a successor.

DR. FRED. C. ZAPFFE has been appointed professor of histology in the medical school of the University of Illinois.

DR. WALTER T. KRETZ has been appointed lecturer in astronomy in Columbia University.

W. SMYTHE JOHNSON, Ph.D. (Yale), has been appointed to the chair of psychology in the State Normal School at Natchitoches, and Dr. Matataro Matsumoto, assistant in the psychological laboratory of Yale University, has been appointed professor of psychology in the Imperial Normal School of Tokyo, Japan.

MR. P. V. BEVAN has been appointed an assistant demonstrator in physics at Cambridge University, and Mr. H. A. Wilson, has been elected to the Clerk Maxwell studentship in experimental physics.

MR. W. H. WILLCOX, M.B., B.Sc. (Lond.), has been elected to the post of lecturer on chemistry and physics at St. Mary's Hospital Medical School, London.

DR. G. C. SCHMIDT, of Eberswalde, has been elected to an associate professorship of theoretical physics in the Univerity of Erlangen. Dr. H. Boruttan, docent in the University of Göttingen, has been promoted to a professorship of physiology. Dr. Heyn, o the Mechanical Institute of Berlin, has been appointed professor of engineering in the Technical Institute at Stuttgart. At the same institution Dr. Englisch has qualified as docent in scientific photography. Dr. Max Reess, professor of botany in the University of Erlangen, has retired.

THE MIND OF PRIMITIVE MAN.*

ONE of the chief aims of anthropology is the study of the mind of man under the varying conditions of race and of environment. The activities of the mind manifest themselves in thoughts and actions, and exhibit an infinite variety of form among the peoples of the world. In order to understand these clearly, the student must endeavor to divest himself entirely of opinions and emotions based upon the peculiar social environment into which he is born. He must adapt his own mind, so far as feasible, to that of the people whom he is studying. The more successful he is in freeing himself from the bias based on the group of ideas that constitute the civilization in which he lives, the more successful he will be in interpreting the beliefs and actions of man. He must follow lines of thought that are new to him. He must participate in new emotions, and understand how, under unwonted conditions, both lead to actions. Beliefs, customs, and the response of the individual to the events of daily life, give us ample opportunity to observe the manifestations of the mind of man under varying conditions.

The thoughts and actions of civilized man and those found in more primitive forms of society prove that, in various

* Address of the retiring president before the American Folk-Lore Society, Baltimore, Dec. 27th.

groups of mankind, the mind responds quite differently when exposed to the same conditions. Lack of logical connection in its conclusions, lack of control of will, are apparently two of its fundamental characteristics in primitive society. In the formation of opinions, belief takes the place of logical demonstration. The emotional value of opinions is great, and consequently they quickly lead to action. The will appears unbalanced, there being a readiness to yield to strong emotions, and a stubborn resistance in trifling matters.

In the following remarks I propose to analyze the differences which characterize the mental life of man in various stages of culture. It is a pleasant duty to acknowledge here my indebtedness to my friends and colleagues in New York, particularly to Dr. Livingston Farrand, with whom the questions here propounded have been a frequent theme of animated discussion, so much so, that at the present time I find it impossible to say what share the suggestions of each had in the development of the conclusions reached.

There are two possible explanations of the different manifestations of the mind of man. It may be that the minds of different races show differences of organization; that is to say, the laws of mental activity may not be the same for all minds. But it may also be that the organization of mind is practically identical among all races of man; that mental activity follows the same laws everywhere, but that its manifestations depend upon the character of individual experience that is subjected to the action of these laws.

It is quite evident that the activities of the human mind depend upon these two elements. The organization of the mind may be defined as the group of laws which determine the modes of thought and of action, irrespective of the subject matter of mental activity. Subject to such laws are the manner of discrimination between perceptions, the manner in which perceptions associate themselves with previous perceptions, the manner in which a stimulus leads to action, and the emotions produced by stimuli. These laws determine to a great extent the manifestations of the mind.

But, on the other hand, the influence of individual experience can easily be shown to be very great. The bulk of the experience of man is gained from oft-repeated impressions. It is one of the fundamental laws of psychology that the repetition of mental processes increases the facility with which these processes are performed, and decreases the degree of consciousness that accompanies them. This law expresses the well-known phenomena of habit. When a certain perception is frequently associated with another previous perception, the one will habitually call forth the other. When a certain stimulus frequently results in a certain action, it will tend to call forth habitually the same action. If a stimulus has often produced a certain emotion, it will tend to reproduce it every time.

The explanation of the activity of the mind of man, therefore, requires the discussion of two distinct problems. The first bears upon the question of unity or diversity of organization of the mind, while the second bears upon the diversity produced by the variety of contents of the mind as found in the various social and geographical environments. The task of the investigator consists largely in separating these two causes and in attributing to each its proper share in the development of the peculiarities of the mind. It is the latter problem principally which is of interest to the folk-lorist. When we define as folklore the total mass of traditional matter present in the mind of a given people at any given time, we recognize that this matter must influence the opinions and activities of the people more or less according to

its quantitative and qualitative value, and also that the actions of each individual must be influenced to a greater or less extent by the mass of traditional material present in his mind.

We will first devote our attention to the question, Do differences exist in the organization of the human mind? Since Waitz's thorough discussion of the question of the unity of the human species, there can be no doubt that in the main the mental characteristics of man are the same all over the world; but the question remains open, whether there is a sufficient difference in grade to allow us to assume that the present races of man may be considered as standing on different stages of the evolutionary series, whether we are justified in ascribing to civilized man a higher place in organization than to primitive man. In answering this question, we must clearly distinguish between the influences of civilization and of race. A number of anatomical facts point to the conclusion that the races of Africa, Australia, and Melanesia, are to a certain extent inferior to the races of Asia, America and Europe. We find that on the average the size of the brain of the negroid races is less than the size of the brain of the other races; and the difference in favor of the mongoloid and white races is so great, that we are justified in assuming a certain correlation between their mental ability and the increased size of their brain. At the same time it must be borne in mind that the variability of the mongoloid and white races on the one hand, and of the negroid races on the other, is so great, that only a comparatively speaking small number of individuals belonging to the latter have brains smaller than any brains found among the former; and that, on the other hand, only a few individuals of the mongoloid races have brains so large that they would not occur at all among the black races. That is to say, the bulk of the two groups of races have brains of the same capacities, but individuals with heavy brains are proportionately more frequent among the mongoloid and white races than among the negroid races. Probably this difference in the size of the brain is accompanied by differences in structure, although no satisfactory information on this point is available. On the other hand, if we compare civilized people of any race with uncivilized people of the same race, we do not find any anatomical differences which would justify us in assuming any fundamental differences in mental constitution.

When we consider the same question from a purely psychological point of view, we recognize that one of the most fundamental traits which distinguish the human mind from the animal mind is common to all races of man. It is doubtful if any animal is able to form an abstract conception such as that of number, or any conception of the abstract relations of phenomena. We find that this is done by all races of man. A developed language with grammatical categories presupposes the ability of expressing abstract relations, and, since every known language has grammatical structure, we must assume that the faculty of forming abstract ideas is a common property of man. It has often been pointed out that the concept of number is developed very differently among different people. While in most languages we find numeral systems based upon the 10, we find that certain tribes in Brazil, and others in Australia, have numeral systems based on the 3, or even on the 2, which involve the impossibility of expressing high numbers. Although these numeral systems are very slightly developed as compared with our own, we must not forget that the abstract idea of number must be present among these people, because, without it, no method of counting is possible. It may be worth while to mention one or two

other facts taken from the grammars of primitive people, which will make it clear that all grammar presupposes abstractions. The three personal pronouns—I, thou, and he—occur in all human languages. The underlying idea of these pronouns is the clear distinction between the self as speaker, the person or object spoken to, and that spoken of. We also find that nouns are classified in a great many ways in different languages. While all the older Indo-European languages classify nouns according to sex, other languages classify nouns as animate or inanimate, or as human and not human, etc. Activities are also classified in many different ways. It is at once clear that every classification of this kind involves the formation of an abstract idea. The processes of abstraction are the same in all languages, and they do not need any further discussion, except in so far as we may be inclined to value differently the systems of classification and the results of abstraction.

The question whether the power to inhibit impulses is the same in all races of man is not so easily answered. It is an impression obtained by many travelers, and also based upon experiences gained in our own country, that primitive man and the less educated have in common a lack of control of emotions, that they give way more readily to an impulse than civilized man and the highly educated. I believe that this conception is based largely upon the neglect to consider the occasions on which a strong control of impulses is demanded in various forms of society. What I mean will become clear when I call your attention to the often described power of endurance exhibited by Indian captives who undergo torture at the hands of their enemies. When we want to gain a true estimate of the power of primitive man to control impulses, we must not compare the control required on certain occasions among ourselves with the control exerted by primitive man on the same occasions. If, for instance, our social etiquette forbids the expression of feelings of personal discomfort and of anxiety, we must remember that personal etiquette among primitive man may not require any inhibition of the same kind. We must rather look for those occasions on which inhibition is required by the customs of primitive man. Such are, for instance, the numerous cases of taboo, that is, of prohibitions of the use of certain foods, or of the performance of certain kinds of work, which sometimes require a considerable amount of self-control. When an Eskimo community is on the point of starvation, and their religious proscriptions forbid them to make use of the seals that are basking on the ice, the amount of self-control of the whole community, which restrains them from killing these seals, is certainly very great. Cases of this kind are very numerous, and prove that primitive man has the ability to control his impulses, but that this control is exerted on occasions which depend upon the character of the social life of the people, and which do not coincide with the occasions on which we expect and require control of impulses.

The third point in which the mind of primitive man seems to differ from that of civilized man is in its power of choosing between perceptions and actions according to their value. On this power rests the whole domain of art and of ethics. An object or an action becomes of artistic value only when it is chosen from among other perceptions or other actions on account of its beauty. An action becomes moral only when it is chosen from among other possible actions on account of its ethical value. No matter how crude the standards of primitive man may be in regard to these two points, we recognize that all of them possess an art, and that all of them possess

ethical standards. It may be that their art is quite contrary to our artistic feeling. It may be that their ethical standards outrage our moral code. We must clearly distinguish between the æsthetic and ethical codes and the existence of an æsthetic and ethical standard.

Our brief consideration of the phenomena of abstraction, of inhibition and of choice, leads, then, to the conclusion that these functions of the human mind are common to the whole of humanity. It may be well to state here, that, according to our present method of considering biological and psychological phenomena, we must assume that these functions of the human mind have developed from lower conditions existing at a previous time, and that at one time there certainly must have been races and tribes in which the properties here described were not at all, or only slightly, developed; but it is also true, that among the present races of man, no matter how primitive they may be in comparison with ourselves, these faculties are highly developed.

It is not impossible that the degree of development of these functions may differ somewhat among different types of man; but I do not believe that we are able at the present time to form a just valuation of the power of abstraction, of control and of choice among different races. A comparison of their languages, customs, and activities suggests that these faculties may be unequally developed; but the differences are not sufficient to justify us in ascribing materially lower stages to some peoples, and higher stages to others. The conclusions reached from these considerations are therefore, on the whole, negative. We are not inclined to consider the mental organization of different races of man as differing in fundamental points.

We next turn to a consideration of the second question propounded here, namely, to an investigation of the influence of the contents of the mind upon the formation of thoughts and actions. We will take these up in the same order in which we considered the previous question. We will first direct our attention to the phenomena of perception. It has been observed by many travelers that the senses of primitive man are remarkably well trained, that he is an excellent observer. The adeptness of the experienced hunter, who finds the tracks of his game where the eye of a European would not see the faintest indication, is an instance of this kind. While the power of perception of primitive man is excellent, it would seem that his power of logical interpretation of perceptions is deficient. I think it can be shown that the reason for this fact is not founded on any fundamental peculiarity of the mind of primitive man, but lies, rather, in the character of the ideas with which the new perception associates itself. In our own community a mass of observations and of thoughts is transmitted to the child. These thoughts are the result of careful observation and speculation of our present and of past generations; but they are transmitted to most individuals as traditional matter, much the same as folk-lore. The child associates new perceptions with this whole mass of traditional material, and interprets his observations by its means. I believe it is a mistake to assume that the interpretation made by each civilized individual is a complete logical process. We associate a phenomenon with a number of known facts, the interpretations of which are assumed as known, and we are satisfied with the reduction of a new fact to these previously known facts. For instance, if the average individual hears of the explosion of a previously unknown chemical, he is satisfied to reason that certain materials are known to have the property of exploding under proper conditions, and that consequently the unknown substance has the same qual-

ity. On the whole, I do not think that we should try to argue still further, and really try to give a full explanation of the causes of the explosion.

The difference in the mode of thought of primitive man and of civilized man seems to consist largely in the difference of character of the traditional material with which the new perception associates itself. The instruction given to the child of primitive man is not based on centuries of experimentation, but consists of the crude experience of generations. When a new experience enters the mind of primitive man, the same process which we observe among civilized man brings about an entirely different series of associations, and therefore results in a different type of explanation. A sudden explosion will associate itself in his mind, perhaps, with tales which he has heard in regard to the mythical history of the world, and consequently will be accompanied by superstitious fear. When we recognize that, neither among civilized man nor among primitive man, the average individual carries to completion the attempt at causal explanation of phenomena, but carries it only so far as to amalgamate it with other previously known facts, we recognize that the result of the whole process depends entirely upon the character of the traditional material: herein lies the immense importance of folk-lore in determining the mode of thought. Herein lies particularly the enormous influence of current philosophic opinion upon the masses of the people, and herein lies the influence of the dominant scientific theory upon the character of scientific work.

It would be in vain to try to understand the development of modern science without an intelligent understanding of modern philosophy; it would be in vain to try to understand the history of medieval science without an intelligent knowledge of medieval theology; and so it is in vain to try to understand primitive science without an intelligent knowledge of primitive mythology. Mythology, theology and philosophy are different terms for the same influences which shape the current of human thought, and which determine the character of the attempts of man to explain the phenomena of nature. To primitive man—who has been taught to consider the heavenly orbs as animate beings, who sees in every animal a being more powerful than man, to whom the mountains, trees and stones are endowed with life—explanations of phenomena will suggest themselves entirely different from those to which we are accustomed, since we base our conclusions upon the existence of matter and force as bringing about the observed results. If we do not consider it possible to explain the whole range of phenomena as the result of matter and force alone, all our explanations of natural phenomena must take a different aspect.

In scientific inquiries we should always be clear in our own minds of the fact that we do not carry the analysis of any given phenomenon to completion; but that we always embody a number of hypotheses and theories in our explanations. In fact, if we were to do so, progress would hardly become possible, because every phenomenon would require an endless amount of time for thorough treatment. We are only too apt, however, to forget entirely the general, and, for most of us, purely traditional, theoretical basis which is the foundation of our reasoning, and to assume that the result of our reasoning is absolute truth. In this we commit the same error that is committed, and has been committed, by all the less civilized people. They are more easily satisfied than we are at the present time, but they also assume as true the traditional element which enters into their explanations, and therefore accept as absolute truth the conclusions based on

it. It is evident that, the fewer the number of traditional elements that enter into our reasoning and the clearer we endeavor to be in regard to the hypothetical part of our reasoning, the more logical will be our conclusions. There is an undoubted tendency in the advance of civilization to eliminate traditional elements, and to gain a clearer and clearer insight into the hypothetical basis of our reasoning. It is therefore not surprising, that, with the advance of civilization, reasoning becomes more and more logical, not because each individual carries out his thought in a more logical manner, but because the traditional material which is handed down to each individual has been thought out and worked out more thoroughly and more carefully. While in primitive civilization the traditional material is doubted and examined by only a very few individuals, the number of thinkers who try to free themselves from the fetters of tradition increases as civilization advances.

The influence of traditional material upon the life of man is not restricted to his thoughts, but manifests itself no less in his activities. The comparison between civilized man and primitive man in this respect is even more instructive than in the preceding case. A comparison between the modes of life of different nations, and particularly of civilized man and of primitive man, makes it clear that an enormous number of our actions are determined entirely by traditional associations. When we consider, for instance, the whole range of our daily life, we notice how strictly we are dependent upon tradition that can not be accounted for by any logical reasoning. We eat our three meals every day, and feel unhappy if we have to forego one of them. There is no physiological reason which demands three meals a day, and we find that many people are satisfied with two meals, while others enjoy four or even more. The range of animals and plants which we utilize for food is limited, and we have a decided aversion against eating dogs, or horses, or cats. There is certainly no objective reason for such aversion, since a great many people consider dogs and horses as dainties. When we consider fashions, the same becomes still more apparent. To appear in the fashions of our forefathers of two centuries ago would be entirely out of the question, and would expose one to ridicule. The same is true of table manners. To smack one's lips is considered decidedly bad style, and may even excite feelings of disgust; while among the Indians, for instance, it would be considered as in exceedingly bad taste not to smack one's lips when one is invited to dinner, because it would suggest that the guest does not enjoy his dinner. The whole range of actions that are considered as proper and improper can not be explained by any logical reason, but are almost all entirely due to custom; that is to say, they are purely traditional. This is even true of customs which excite strong emotions, as, for instance, those produced by infractions of modesty.

While in the logical processes of the mind we find a decided tendency, with the development of civilization, to eliminate traditional elements, no such marked decrease in the force of traditional elements can be found in our activities. These are almost as much controlled by custom among ourselves as they are among primitive man. It is easily seen why this should be the case. The mental processes which enter into the development of judgments are based largely upon associations with previous judgments. I pointed out before, that this process of association is the same among primitive man as among civilized man, and that the difference consists largely in the modification of the traditional material with which our new perceptions amalgamate. In the case of activities, the

conditions are somewhat different. Here tradition manifests itself in an action performed by the individual. The more frequently this action is repeated, the more firmly it will become established, and the less will be the conscious equivalent accompanying the action; so that customary actions which are of very frequent repetition become entirely unconscious. Hand in hand with this decrease of consciousness goes an increase in the emotional value of the omission of such activities, and still more of the performance of actions contrary to custom. A greater will power is required to inhibit an action which has become well established; and combined with this effort of the will power are feelings of intense displeasure.

This leads us to the third problem, which is closely associated with the difference between the manifestation of the power of civilized man and of primitive man to inhibit impulses. It is the question of choice as dependent upon value. It is evident from the preceding remarks that, on the whole, we value most highly what conforms to our previous actions. This does not imply that it must be identical with our previous actions, but it must be on the line of development of our previous actions. This is particularly true of ethical concepts. No action can find the approval of a people which is fundamentally opposed to its customs and traditions. Among ourselves it is considered proper and a matter of course to treat the old with respect, for children to look after the welfare of their aged parents; and not to do so would be considered base ingratitude. Among the Eskimo we find an entirely different standard. It is required of children to kill their parents when they have become so old as to be helpless and no longer of any use to the family or to the community. It would be considered a breach of filial duty not to kill the aged parent. Revolting though this custom may seem to us, it is founded on an ethical law of the Eskimo, which rests on the whole mass of traditional lore and custom.

One of the best examples of this kind is found in the relation between individuals belonging to different tribes. There are a number of primitive hordes to whom every stranger not a member of the horde is an enemy, and where it is right to damage the enemy to the best of one's power and ability, and if possible to kill him. This custom is founded largely on the idea of the solidarity of the horde, and of the feeling that it is the duty of every member of the horde to destroy all possible enemies. Therefore every person not a member of the horde must be considered as belonging to a class entirely distinct from the members of the horde, and is treated accordingly. We can trace the gradual broadening of the feeling of fellowship during the advance of civilization. The feeling of fellowship in the horde expands to the feeling of unity of the tribe, to a recognition of bonds established by a neighborhood of habitat, and further on to the feeling of fellowship among members of nations. This seems to be the limit of the ethical concept of fellowship of man which we have reached at the present time. When we analyze the strong feeling of nationality which is so potent at the present time, we recognize that it consists largely in the idea of the preeminence of that community whose member we happen to be,—in the preeminent value of its language, of its customs and of its traditions, and in the belief that it is right to preserve its peculiarities and to impose them upon the rest of the world. The feeling of nationality as here expressed, and the feeling of solidarity of the horde, are of the same order, although modified by the gradual expansion of the idea of fellowship; but the ethical point of view which makes it justifiable at the present time to increase

the well-being of one nation at the cost of another, the tendency to value one's own civilization as higher than that of the whole race of mankind, are the same as those which prompt the actions of primitive man, who considers every stranger as an enemy, and who is not satisfied until the enemy is killed. It is somewhat difficult for us to recognize that the value which we attribute to our own civilization is due to the fact that we participate in this civilization, and that it has been controlling all our actions since the time of our birth; but it is certainly conceivable that there may be other civilizations, based perhaps on different traditions and on a different equilibrium of emotion and reason which are of no less value than ours, although it may be impossible for us to appreciate their values without having grown up under their influence. The general theory of valuation of human activities, as taught by anthropological research, teaches us a higher tolerance than the one which we now profess.

Our considerations make it probable that the wide differences between the manifestations of the human mind in various stages of culture may be due almost entirely to the form of individual experience, which is determined by the geographical and social environment of the individual. It would seem that, in different races, the organization of the mind is on the whole alike, and that the varieties of mind found in different races do not exceed, perhaps not even reach, the amount of normal individual variation in each race. It has been indicated that, notwithstanding this similarity in the form of individual mental processes, the expression of mental activity of a community tends to show a characteristic historical development. From a comparative study of these changes among the races of man is derived our theory of the general development of human culture. But the development of *culture* must not be confounded with the development of *mind*. Culture is an expression of the achievements of the mind, and shows the cumulative effects of the activities of many minds. But it is not an expression of the organization of the minds constituting the community, which may in no way differ from the minds of a community occupying a much more advanced stage of culture.

FRANZ BOAS.

ASSOCIATION OF AMERICAN ANATOMISTS.

THE fourteenth session of the Association of American Anatomists, meeting with the American Society of Naturalists and Affiliated Societies in Baltimore, Md., was held in the Anatomical Laboratory of the Johns Hopkins University, December 27 and 28, 1900.

The meeting was called to order, December 27th at 10:20 A.M., by President George S. Huntington.

The Executive Committee reported and recommended the names of eleven candidates for membership. Also a recommendation that at the discretion of the secretary the first five 'Proceedings,' now out of print, should be reprinted. Also a recommendation that the Association endorse the proposition for the establishment of a psycho-physical laboratory in the Bureau of Education, Washington, D. C.

By unanimous consent the secretary cast the ballot for the nominees for membership. The Association also authorized the secretary to reprint the five 'Proceedings' as recommended. The recommendation to endorse the psycho-physical laboratory was not agreed to and was referred to a committee to be appointed by the president to report at a future meeting. It was discussed unfavorably by Drs. Holmes and Hrdlicka.

The Secretary made his yearly report, which stated, among other things, that he had in hand copies of the 'Proceedings'

of the Association from the 6th to the 13th meeting, which were available for distribution to members and especially to libraries. There were 33 libraries and journals on the regular mailing list. The financial exhibit showed a balance in the treasury of $177.47 ; total receipts $492.25 ; expenditures $314.78. He suggested the desirability of having a summer meeting with the American Association for the Advancement of Science. The Association had lost several members since May, 1900, when a provisional report had been made. Professor Wm. Anderson of London, an honorary member, died Oct. 27th. Dr. A. L. T. Schäper, of Harvard Medical School, had left this country, having been appointed a professor at the University of Breslau, Prussia. There were now 116 active and 9 honorary members, total, 125.

No reports were received from the delegate to the executive committee of the Congress of American Physicians and Surgeons, nor from the committee on anatomical peculiarities of the negro, nor from the committee on table at Naples. The committee on anatomical nomenclature reported progress.

The President appointed a committee consisting of Drs. Huber, Carmalt and Barker to report nominations for delegates to the executive committee of the Triennial Congress and a new member of the executive committee of this Association.

Dr. Huntington then read the Presidential address, taking for his subject 'The Morphological Museum as an Educational Factor in the University System.'

The following papers were read:

The Use of Wet Specimens: Dr. Holmes, Philadelphia.

The cry of the general public for practicability and the desire of the recent graduate for rapid success, and strangely enough the theory of our medical schools, 'science for its own sake,' are all tending to the same point, namely, the training of students to be scientists before they have been educated as physicians. As a resultant of these forces, our medical schools are getting away from their original intent of turning out practising physicians and are evolving one-sided specialists, which again, strangely enough, the tendency to laboratory and section teaching only seems to increase, by compelling men to choose certain subjects to the exclusion of others. Following this has come a disinclination to instruct and a neglect of teaching method, so that, as has been said in anatomy, 'a man who has a book, a subject and a scalpel, ought to be able to work it all out for himself.' The most obvious improvement in our branch is the teaching in small sections ; next the methodical daily apportionment of the work. If we could have our way, we would not only assign the same dissection for the same hour, but if it were possible we would have our scalpels ply together with the same unison as the violin bows in a well-trained orchestra. To be ahead of the assignment is a crime, to be behind it far better, if it implies not sloth nor ignorance, the most careless students being the most rapid slashers. Methodical and clean dissection implies a foreknowledge of the structure, but it is difficult to impress the fact that the dissecting room is a laboratory and not a library alcove, didactic reading should be done at home, the only use of the book being in connection with the cadaver. Explanations should be from the wet specimen and not merely a worded exposition. The wet specimen of muscle, artery or joint should be kept continually before the student as a pattern, to supply the defects of his own work, to study the deeper connections or to review the more superficial which must necessarily be cut away and, at the conclusion of the dissection, for a review of the whole part. Equally for the alumnus

dissector whose time is limited. With a book upon applied anatomy such hurried practitioners with a dissected subject before them can get ten times more practical benefit than could possibly be accomplished by an individual not an expert. If we were given a choice with the average man between a course of study upon the cadaver with carefully prepared wet specimens and the hacked up dissection, we should without hesitation recommend the former. For intelligent comprehension, based on sound pedagogical principles, instruct your student, first, as to what to find, and where, 'in the wet,' and then careful, neat, systematized dissection can not be done too often. For the preservation of wet specimens cold storage is by far the best, with the '*Kaiserling*' next. Alcohol hardens them too much, solutions of chloral waterlog them, formalin preparations favor mold of any part from which the fluid is allowed to evaporate.

Dr. Corson, of Savannah, Ga., not being able to be present, his paper, '*The Value of the X-ray in the Study of Normal Anatomy*,' illustrated by photographs of the human membral epiphyses at the thirteenth year, was read by Dr. Kerr of Cornell University. The paper contended that the X-ray would prove of value, first, in the study and demonstration of bone development the growth of the epiphyses, the schema of their development and the study of joints as joints, with their movements; second, in the demonstration of the internal structure of the bones; third, in the study and demonstration of the exact spacings and positions of the bones in the skeleton as a guide to its proper articulation and mounting; this would find its widest application in comparative osteology; fourth, in the study and demonstration of the arteries on the cadaver, where properly injected, they can be skiagraphed in their absolute relations to other structures. The possibility of this work is wholly due to great improvements in apparatus and technique, and without doubt we can look for even greater improvements in the future in X-ray intensity, which will widen its present field of usefulness. By the X-ray we can really watch the bones grow, and we get certain projected plans of bones and their exact positions in the skeleton which give us new ideas of function as well as of form. Thus physiology as well as morphology will benefit by the discovery of Röntgen.

The Levator Ani Muscle: DR. HOLMES, Philadelphia.

The levator ani muscle arises internal to the obturator fascia, on a line from the posterior surface of the crest of the pubes to the spine of the ischium; the fibrous leaf-lets, projecting proximal and distal to the muscle, and running downwards and inwards parallel to its fibers, being called the recto-vesical and anal fascias, which for our purpose form a sheath for the levator ani, but in reality constitute the true supporting floor of the pelvic outlet. The levator ani muscle in its origin is unique. At its insertion it is fixed only at the perineal center and the coccyx, while at the median raphe it is movable throughout, though counterbalanced by its fellow of the opposite side; and at the sphincters it is as yielding as the soft viscera themselves. None of the fibers are attached to the prostate gland, though they go behind it to join with the opposite muscle constituting a compressor as well as a levator prostatæ; so to the sphincters of the anus and of the vagina we can trace the muscular fibers, but not to the walls of the vagina nor of the rectum. The recto-vesical fascia which forms the proximal side of the muscular sheath blends with the fibrous coat of each canal, but the only direct interlacement of the muscular fibers is with the sphincters.

It would seem, therefore, as if the authors were in error in asserting that the levator ani is inserted 'into the lateral aspect of the prostate,' 'into the side of the rectum' or 'into the walls of the vagina,' but as in its origin, the muscles are attached to a narrow linear movable insertion.

It is more a tensor of the fascia, either at its origin or insertion, the fixed point being interchangeable, so that it should be called the 'Tensor perineæ' rather than 'Levator ani.'

Development of the Human Diaphragm: Dr. Mall, Baltimore. (Illustrated by diagrams and specimens.)

In human embryos four weeks old the pericardial and peritoneal cavities freely communicate. At this time, however, a ridge of tissue is formed in the wall of the cœlom opposite the ductus Cuvieri and cardinal veins which grows rapidly and encircle the lungs to form the pulmonary ridge. A week later the ridge widens to form the beginning of two membranes. The first of these, the pleuro-pericardial membrane, contains within it the phrenic nerve and soon separates the pleural from the pericardial cavity. The second, the pleuro-peritoneal membrane, grows towards the tail with the rotation of the liver and the degeneration of the Wolffian body, and at the end of the sixth week completes the diaphragm.

Dr. Stroud, of Cornell University, was unable to be present. A photograph sent by him, showing *apparatus for demonstrating the circulation of the blood*, was passed around among the members.

The apparatus is an imitation of the actual blood vascular system. The heart, arteries, capillaries and veins are represented by a rubber bulb with valves, very elastic rubber tubing; capillary glass tubing and thinner rubber tubing. The bifurcation of arteries is shown in Y-shaped, of veins by U-shaped, glass tubes. The circulation is continuous as in the living body. Manometer tubes indicate the difference in pressure in arteries and veins.

Advantages and Limits of the Methods of Reconstruction with Wax Plates in Anatomical and Embryological Investigations. Dr. Chas. R. Bardeen, Baltimore. (Illustrated by specimens, etc.)

Discussed by Drs. Huber, Minot, Barker, W. S. Miller and Huntington.

Demonstration of a New Freezing Microtome: Dr. Bardeen.

Specimen of Cyclopia: Dr. Carmalt, New York City. (With cast and photographs.) Discussed by Dr. Minot.

A Caudal Appendage in a Human Infant: Dr. Harrison, Baltimore. (Illustrated by specimen and photographs.)

Discussed by Dr. Hrdlicka. A tail-like appendage, measuring $2\frac{1}{4}$ inches in length, was present in an infant of four months. The tail arose close to the tip of the coccyx, although not a direct continuation of the latter. It contained no cartilage nor bone, but did contain voluntary muscle fibers, and was movable to a considerable degree.

Typical Forms of Shaft of Long Bones other than the Tibia: Dr. Hrdlicka, New York City. (Illustrated by specimens.)

Discussed by Drs. Huber and Huntington. The paper presents the further results of the writer's investigations on Professor Huntington's osteological collection in the Medical Department of Columbia University, New York City. It deals with the variations in shape of long bones and classification of these shapes in a similar manner as the former (1898) communication on the tibia. An inference will be drawn as to the causes of the variation.

Notes on the First and Second Ribs and a Demonstration of Bicipital, Bicaudal, Notched and Perforated Ribs in Man; also Notes and

Articulation of Ribs with each other: DR. HRDLICKA. (Illustrated by specimens.)

Discussed by Dr. Huntington. Variations in shape of normal first and second ribs; the scalene tubercle, its frequency and real nature, and a similar tubercle on the second rib; peculiarity of the normal ossification of the cartilage of first rib. Demonstration of anomalous specimens.

Variations of the Inferior Cava: DR. HUNTINGTON. (Illustrated by photographs.)

The Origin of the Lymphatics of the Liver: DR. MALL.

When Prussian-blue gelatin in which cinnabar is suspended is injected into either the portal or hepatic vein, it is found that the blue filters through the capillary wall, leaving the red granules in the capillaries. The capillaries are surrounded by the perivascular lymph spaces which communicate with perilobular lymph spaces. These, in turn, communicate freely with the interlobular lymphatics.

The Lobule of the Lung: DR. W. S. MILLER, Madison, Wis. (Illustrated by models, diagrams and lantern slides.)

Discussed by Drs. Huntington and Huber. The term lobule as applied to the unit of the lung has been used in an exceedingly vague sense both by anatomists and pathologists. It is the purpose of the paper to give a definite meaning to the term.

The Epithelium of the Pleural Cavities: DR. MILLER, Madison, Wis. (Illustrated by lantern slides and preparations.)

Since the time of v. Recklinghausen and Oedmansson certain dark spots seen in many preparations of serous membranes stained by the silver nitrate method have been called *stomata* and *stigmata*. Ludwig and Dybkowsky described such structures in the pleura. Muscatello has recently shown that such openings do not exist normally in the peritoneum. It is the purpose of the paper to show that they do not exist in the pleura when studied in the normal condition, and that they can be produced artificially at the pleasure of the investigator.

Preliminary Report with Projection Drawings, illustrating the Topography of the Paracœles in their Relation to the Surface of the Cerebrum and Cranium: MR. E. A. SPITZKA, New York City. (Illustrated by drawings and diagrams.)

Since the tapping and injecting into the ventricles have become definite procedures in surgery, it would greatly aid the operator to have a more accurate conception of the extent, depth and contour of the cavities, with their variations, than can be had from the bare rules and measurements set forth in most surgeries. With this view the author utilizes the entire head, hardened by injection of, and submersion in, formal. After a time the cranium is opened and the brain is accurately sliced, correct drawings being made at each step and projected for the delineation of the final plates. Two heads have so far been completed. It is proposed to decalcify the skulls of subsequent material, the entire head being then subjected to the slicing method. [Published in *New York Medical Journal*, February, 2, 1900.]

Bilateral Relations of the Cerebral Cortex: DR. MELLUS, Baltimore.

Hastily reviewing bilateral relations previously demonstrated, he called attention to a series of his recent experiments on the monkey. After extirpation of a small portion of cortex from that part of the so-called motor area situated on the boundary line between facial and upper limb centers, he showed degenerated fibers passing from the lesion across the middle line in the corpus callosum. These fibers were distributed to cortical areas of the opposite hemisphere corresponding to the convolutions upon the

side of the lesion, to which association fibers were traced directly from the lesion. This distribution of association fibers to the convolutions of the two hemispheres was quite symmetrical, and by far the greater number passed to that portion of the opposite hemisphere which corresponded to the situation of the lesion. In addition to these association fibers a large portion of the degenerated tract crossing in the corpus callosum turned down into the internal capsule of the opposite side. These fibers mostly terminated in the thalamus and hypothalamus, but in a number of instances a few of these fibers passed on through the pons and medulla into the cord. Owing to the degeneration in both pyramids above the decussation, it could not be determined whether or not these fibers recrossed in the decussation. Dr. Mellus stated that after unilateral lesions in the brain of the dog he had found fibers crossing in the corpus callosum and passing down the internal capsule of the opposite side. In no instance, however, had he found these fibers in the dog passing through the capsule. They all passed out of the capsule and ended in the thalamus of the side opposite the lesion.

Methods of Statistical Study in the Dissecting Room with special reference to the Peripheral Nervous System: DR. BARDEEN. (Illustrated by charts.)

Discussed by Dr. Huntington.

Wandering of the Skin during Development, in Relation to the Distribution of Cutaneous Nerves: DR. HARRISON. (Illustrated by diagrams.)

By a process of transplantation, embryos of two species of frogs may be combined, and through contrast in pigmentation, wandering of the epidermis may be accurately observed as the embryo develops. There is a definite relation between this movement and the course of the cutaneous nerves in the adult. The wandering of the skin is, at least to a great extent, passive, and is due to mechanical causes.

Intrinsic Blood Vessels of the Kidney and their Significance in Nephrotomy: MR. MAX BRÖDEL, Baltimore.

The pelves of most kidneys are on the posterior part of the hilum and pass obliquely forward to the center of the kidney. The calices are grouped in two rows, anterior, pointing forward, and a posterior, pointing laterally. The arteries usually divide into two main trees, an anterior, carrying three-fourths to four-fifths of the blood, and a posterior furnishing the remainder. There is neither anastomosis nor crossing between the branches of these two trunks; they are completely separated by the pelvis and its calices. The superficial and deep collecting veins of the cortex empty into the venous arches at the base of the pyramids, forming the peripheral system of venous anastomoses. There is, however, a second more central system around the necks of the calices. Practically all the veins at the hilum pass anteriorly to the pelvis. The form of the pyramids and their relations to the blood vessels and surface, and also the columns of Bertini, have been studied. Although many kidneys deviate in their construction, all conform more or less to the rules mentioned. The studies reveal several points of interest to the surgeon, among which are: (1) The most advantageous incision for nephrotomy. (2) The appropriate method of suturing an incised kidney. (3) A very satisfactory method of fixing the kidney. (4) The insufficiency of the method of opening the pelvis at the hilum.

Histology of the Endometrium: DR. T. S. CULLEN, Baltimore. (Illustrated by specimens and drawings.)

The Architecture of the Gall-bladder: DR. M. T. SUDLER, Baltimore. (Read by title.)

The Classification of Glands: DR. MINOT, Boston. (Read by title.)

Contribution to the Question of Fissural Integrality of the Paroccipital; Observations on 100 Brains: MR. SPITZKA. (Illustrated by drawings.)

Examination of 100 brains in the anatomical laboratory of the College of Physicians and Surgeons, New York City, yielded results similar to those of Professor Wilder. The question of the integrality, with the hypotheses of Cunningham, Wilder and Parker, are briefly discussed. The writer inclines to the opinion that it is not an integer, but a partial and modified segment of the simian exoccipital; and, further, that its confluence with, or separation from, the parietal should be regarded as of secondary significance and importance.

The Mesial Relations of the Inflected Fissure. Observations on 100 Brains: MR. SPITZKA. (With about 60 illustrations.)

The chief points are: (1) the normal position of the inflected fissure on the meson is caudad of the cephalic limb of Wilder's paracentral fissure in other words, its mesial portion indents and partly lies within the paracentral lobule (or as Broca prefers to call it, 'oval lobule'). (2) There is considerable confusion in modern encephalic literature concerning the synonymy of the inflected fissure. The most erroneous statements come from Eberstaller, and consist in a misinterpretation of Broca's 'incisure pré-ovalaire' and Schwalbe's 'sulcus paracentralis,' with the 'inflected fissure' of Lussana and Wilder, 'X-fissure' of Benedict and Flesch, or 'sulcus præcentralis medialis' of Eberstaller and other European writers. Broca's and Schwalbe's fissure corresponds to the cephalic limb or limiting ramus of Wilder's paracentral. (3) The condition presented in the mulatto brain described by Wilder (see Figs. 4766 and 4772 of his article, *Handbook*, Vol. VIII., 1889) is anomalous and rare, since the inflected appears wholly without the paracentral gyrus, and therefore cephalad of Broca's 'pre-oval incisure' or Wilder's cephalic paracentral limb. The explanation appears to be that the cephalic limb is obliterated, while simultaneously one of the intraparacentral elements, of which there seem to be several, has effected a junction with the paracentral stem, and thus appears, at first glance, to be a well-defined cephalic ramus.

The Brains of Two Distinguished Physicians, Father and Son; a Comparative Study of their Fissures and Gyres: MR. SPITZKA. (Illustrated by drawings and photographs.)

Discussed by Drs. Lamb and Huntington. The paper treats carefully and at length of the brains of Dr. Edouard Seguin and his son, Dr. Edward C. Seguin. The learning and progressiveness of these men are well known in the educational and scientific world. Both were interested in the study of idiocy and medical thermometry; the father was especially instrumental in introducing the metric system into this country, while the son, as one of the pioneers of American neurology, made many valuable contributions to the pathology and therapeutics of nervous diseases. The brains show a general similarity and refined development, but with differences as puzzling as profound; and many interesting features appear in the comparison. So far as the author knows, this is the first instance in which the brains of blood relatives have been compared and described.

Method of Utilizing Frozen Sections for Class-Demonstrations of Visceral Anatomy and the Epiphyses: PROFESSOR PRIMROSE, Toronto, Canada.

The exhibition of lantern slides was a series of photographs made from sections through the trunk and extremities of chil-

dren. The sections were prepared in a special manner so as to present a perfectly smooth surface with clear outlines of the various structures. These sections were photographed and lantern plates made from the negatives. They were cut in sagittal, coronal and horizontal planes through the trunk, and in longitudinal and transverse directions through the extremities. The method adopted in the University of Toronto is that permanent preparations are made of the sections, which are mounted in flat dishes, and thus exposed, so that they are accessible for the students at any time in the Anatomical Department. The lantern demonstration of these sections is given from time to time at the close of a lecture. It proves to be a very useful adjunct to the ordinary methods of demonstration, and the student always has the opportunity of studying the actual section in the dissecting room, the photograph of which is thrown upon the screen in the lecture theater. It is claimed that these photographs of actual sections are of much greater value from an educational standpoint than the drawings reproduced from the sections.

Method of Teaching the Anatomy of the Central Nervous System to Large Classes of Students: DR. BARKER, Chicago, Ill. (Read by title.)

D. S. LAMB,
Secretary.

THE ELEVENTH MEETING OF THE AMERICAN MORPHOLOGICAL SOCIETY.

THE American Morphological Society held its eleventh annual meeting in the Anatomical Laboratory of Johns Hopkins University, on the 27th and 28th of last December. A good proportion of members was present.

The following officers were elected for the present year: *President,* J. S. Kingsley; *Vice-President,* E. A. Andrews: *Secretary-Treasurer,* Thos. H. Montgomery Jr.; *Members of the Executive Committee,* C. F. W. McClure and C. W. Hargitt. Twelve new members were elected; and the Society voted fifty dollars for the support of the University table at the Naples laboratory.

The following papers were read (abstracts of which will be published in the *Biological Bulletin*):

Fission and Regulation in Stenostoma leucops: C. M. CHILD.

On Gunda segmentata in America: W. C. CURTIS.

Exhibition of Pacific Coast Nemerteans: W. R. COE.

Some Disputed Points in the Anatomy of Limpets: M. A. WILLCOX.

The Habits and Life History of Argulus, with reference to its Economic Relations: C. B. WILSON.

A Comparative Study of the Development of the Germinative Tract of Termites: H. MCE. KNOWER.

The Anatomy and Development of the Vena cava in Didelphys Virginiana: C. F. W. MCCLURE.

The Crossing of the Optic Nerves in Teleosts: G. H. PARKER.

A New Type of Budding in Annelids: H. P. JOHNSON.

Amphibian Studies: J. S. KINGSLEY.

Phagocytosis in a Mammalian Ovary: M. M. METCALF.

The Mammalian Lower Jaw: W. H. RUDDICK and J. S. KINGSLEY.

An Apparatus in the Central Nervous System of Vertebrates for the Transmission of Motor Reflexes arising from Optical Stimuli: P. E. SARGENT.

The Structure of the Testis in Desmognathus fuscus: B. F. KINGSBURY.

The Synapsis Stage of the Germ Cells: T. H. MONTGOMERY, JR.

A Study of the Phenomena of Cleavage in Etherized Eggs : E. B. WILSON.

The Influence of the Germ Cells upon the Somatic Cells: G. W. FIELD.

Two Improved Forms of Automatic Microtomes: C. S. MINOT.

A Study of the Phenomena involved in the Chemical Production of Parthenogenesis in Sea Urchins: E. B. WILSON.

Centrosomes and Spheres in the Maturation, Fertilization and Cleavage of Crepidula: E. G. CONKLIN.

Independence of the Germ Nuclei in Cleavage.

A New Method of Preservation of Fragile Specimens: A. D. MEAD.

Larval Stages and Metamorphosis of the Hermit Crab: M. T. THOMPSON.

Regeneration in Planaria maculata: C. W. BARDEEN.

Histogenesis of the Peripheral Nervous System in Salmo salar: R. G. HARRISON.

The Mesentric and Spermatic Arteries of Didelphys Virginiana: C. F. W. MCCLURE.

Observations upon the Regeneration of Renilla: H. B. TORREY.

Certain Points in the Structure of the Lower Vertebrate Brain: J. B. JOHNSON.

Asexual Reproduction of Planaria maculata W. C. CURTIS.

Variation in Hydromedusæ: C. W. HARGITT.

The relative Proportion of the Sexes in Poultry: G. W. FIELD.

Notes on Variation in the Shells of Purpura capillus: R. P. BIGELOW and H. S. CONANT.

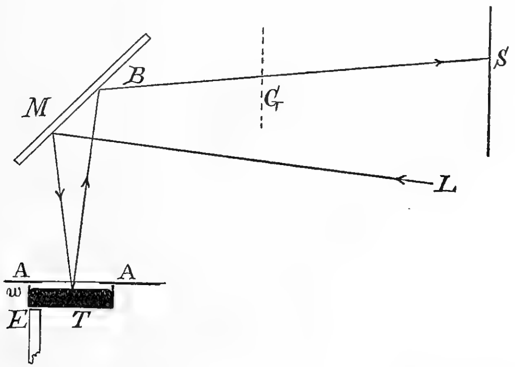
Variation and Elimination in Philosamia cynthia: H. E. CRAMPTON.

The Tentacles of Gonionemus: H. F. PERKINS.

THOS. H. MONTGOMERY, JR.,
Secretary.

THE PROJECTION OF RIPPLES BY A GRATING.

AFTER obtaining the condition under which one grating is projected by another, it seemed not unlikely that the method might be used for projection of ripples. If the latter are obtained in a trough of rectangular outline, the light reflected from them breaks up into two series of equi-



distant bright lines intersecting each other orthogonally. Hence the first grating* may be dispensed with, being replaced by

*See preceding article, SCIENCE, XII., pp. 617–627, October 26th, 1900. The bars of the grating *G* must be parallel to the projection of ripples at *S*, both being vertical lines like the axis of *G*.

the illuminated ripples which are then projected by the second grating. In the figure sunlight arriving at L is reflected from the large mirror M (one foot square), passing thence to and from the shallow rectangular trough T, containing mercury, to be again reflected by M, to the screen S. If a lens is placed at B, so that T is the conjugate focus of S, magnificent ripple patterns are seen on the screen whenever the table is slightly jarred by drumming on it with the fingers. These are stationary capillary waves originating at each of the straight edges of the trough. They may be obtained in different wave lengths in the ratio of 1:2, according as the table is more or less sharply rapped. Gravitational waves, though always markedly present, do not appear in the picture and may be ignored. To produce them observably it is necessary to have some special device for starting them. Two or three straight iron or steel wires, lying stably at w, on the capillary edge of the trough, are an excellent wave producer if controlled by the electromagnet E. Among interesting experiments of this kind I will only mention the reflection of waves, which advance with a crest and return with a trough, from a fixed obstacle, the lines in the image being respectively light and dark. It takes some practise, however, to see this, for with troughs as shallow as convenient the velocity will not lie much within six inches or a foot per second.

Returning from this digression, let the lens be removed and replaced by a grating, G, capable of rotation about a vertical axis. When the proper angle is obtained, a fairly sharp image of the ripples may be seen whenever the table is jarred. Care must be taken to avoid errors due to the diffraction by the grating of the light issuing from the round capillary edge of the mercury in T. These lines of light give rise to extensive streamers on the screen, intersected by sharp diffraction cross bands, the streamers intersecting each other at right angles in the patch of light due to the mercury surface proper. Hence an annular screen, AA, is added to blot out the convex edges.

If x is the (broken) distance between mercury and grating, G, if y is the distance between grating and screen, θ, the azimuth angle of G for which the image appears sharpest, finally if a is the distance apart of the ripples and b the grating space, the relation $a = b \cos\theta\,(1 + x/y)$ is available. To give an example of experiments tried in this way, I found roughly, $x = 105$ cm., $y = 670$ cm., $b = .21$ cm., $\theta = 30°$, whence $a = .2$ cm.

If the trough T is long (say two feet long and three inches broad), the waves from the end are dampened out before they reach the middle, and the cross waves are alone in presence there. These lines of light, if the long edge is parallel to the direction of projection, give sharper images. I have not yet, however, been able to develop this method to a degree useful for measurement, and I merely communicate it here as an interesting experiment. I may note, in conclusion, that if progressive instead of stationary ripples be produced, and if the grating move in a direction opposite to the ripples, with a velocity increasing until the shadow bands moving in the first instance become stationary, the velocity of the ripples would be deducible as well as their wave length.

C. Barus.
Brown University, Providence, R. I.

REVIEWS OF CURRENT BOTANICAL LITERATURE.

A little more than a year ago at the annual meeting of the Society for Plant Morphology and Physiology, held in New Haven, a committee, consisting of Dr. Farlow of Harvard University, Dr. MacDougal of the New York Botanical Garden and Dr.

von Schrenk of the Missouri Botanical Garden, was appointed to consider the question of securing better reviews of current botanical literature. A preliminary report was made by this Committee last June, at a special meeting of the Society held in New York at the time of the meeting of the American Association for the Advancement of Science. In this report the committee includes the correspondence between the secretary of the Society, Professor Ganong of Smith College, and Dr. Oscar Uhlworm of Cassel, Germany, the Editor-in-Chief of the *Botanisches Centralblatt*. Realizing that the aim of the *Centralblatt* is to publish such reviews and that it is inadvisable to multiply journals, the committee suggested some changes in the plan and management of that publication. In the words of Professor Ganong's letter:

The chief cause of dissatisfaction with the *Centralblatt* in this country is its policy of publishing only a part of the reviews in the *Centralblatt* itself, relegating the remainder to *Beihefte*, for which a considerable additional subscription must be paid. If this were rendered necessary by the number of the reviews there could be no objection to it, but obviously the additional reviews necessitating the *Beihefte* are crowded out by the publication of the *Originalmittheilungen*. Those who subscribe for the *Centralblatt* do so for the sake of the reviews and announcements of new literature, and not for the original articles, which have no logical place in a journal devoted to reviews. The Committee feels assured that the relegation of the *Originalmittheilungen* to the *Beihefte*, or their omission altogether, and the inclusion of all the reviews in the *Centralblatt* itself would make the *Centralblatt* much more widely and completely acceptable to botanists. They believe, also, that the increased support which would be given it would compensate for any loss of subscriptions by the cessation of the *Beihefte*, and also (and this they regard as of much importance) it would tend to prevent the appearance of any competing journal.

In regard to matters of detail the committee's letter continues:

The Committee, with other botanists, believes that the reviews of a journal devoted to communicating the appearance of new literature should be, above all, *prompt* and *descriptive*. What botanists mainly wish to learn from reviews is whether the work reviewed is important to their particular interests, and what its contribution is to the science as a whole. The abstracting of the contents of a book or paper in detail seems rather to belong to such a work as Just's *Jahresbericht*, and may well be left to it, thus shortening the descriptive reviews, and making it the easier to include them all within the limits of a journal without the need for *Beihefte*. Promptness in the appearance of reviews is particularly desirable, particularly to those who live at a distance from the place of publication.

The reply to this communication, while encouraging, was not all that the committee desired. Thus, while the editors of the *Centralblatt* were willing to confine the reviews to the journal itself, relegating the original articles to the *Beihefte*, they wished to be guaranteed a certain annual subsidy, and to still retain the right to require the subscriber to pay for both *Centralblatt* and *Beihefte*. To these stipulations the committee very properly demurred, and after discussing other proposed plans, *e. g.*, the printing of such reviews in the form of a card catalogue, or the establishment of a new journal, asked for more time for further consultation with the publishers and editors of the *Centralblatt*.

Accordingly a second interchange of letters was had, and the results were laid before the Society as a second report, in December last, during the annual meeting held in Baltimore. Professor Ganong's letter is as follows (omitting some formal matters which need not be repeated here):

The Committee has given very careful consideration to the letter of the editors and publishers of the *Centralblatt*, and has gathered all available data from the discussions of the society and by correspondence with many botanists in America and elsewhere. As a result the Committee has to present the following

reply to the propositions contained in your recent letter:

1. You propose that, in return for certain specified changes in the *Centralblatt*, a certain annual subsidy (or else a certain number of subscriptions) to the *Centralblatt* shall be guaranteed by this Committee or by some other body of American botanists. The Committee is firmly assured that such a guarantee in either form could not secure the support of any botanical organization in this country, and hence regards it as useless to consider this point further.

2. Your offer to increase the size of the *Centralblatt* from 104 to 129 Bogen yearly does not appear to the Committee an improvement in the direction desired by American botanists. As pointed out on page 6 of the report, there is no dissatisfaction on the score of relatively insufficient attention to American literature, and hence no reason on that account for an increase in the size of the *Centralblatt*.

3. You propose to separate the *Referate* from the *Originalmittheilungen* and to publish *Referate* in one *Abtheilung*, and *Originalmittheilungen* and *Neue Litteratur* in another, the two, however, not to be obtainable separately by subscribers. While the proposed separation has certain advantages, its value is practically entirely destroyed by the condition that the two *Abtheilungen* cannot be subscribed for separately. The Committee regards it as an indispensable condition to the future active support of the *Centralblatt*, or any other journal of like aims, that it shall be possible to subscribe for *Referate* and *Neue Litteratur* without being obliged to pay for *Originalmittheilungen*, which have no logical place in a journal devoted to reviews.

4. You propose the establishment of an American Board of Editors. This proposition has been received by the Committee, and as well by the members of the Society and by other botanists, with much satisfaction. The opinion appears to be general that such a step would contribute greatly to make the *Centralblatt* acceptable to American botantists.

The Committee finds itself obliged to state, therefore, that in its opinion no change in the *Centralblatt* will make it acceptable to American botanists which does not permit of subscribing for *Referate* and *Neue Litteratur* without having to pay for *Originalmittheilungen*. If this change were made in the *Centralblatt*, and if an American Board of Editors were appointed as proposed by you, the Committee has no doubt that the minor reforms, the need for which was referred to in its former letter, could gradually and satisfactorily be brought about. Such changes would remove all reason for the existence of another and competing journal, and would, in the opinion of the Committee, attract to the *Centralblatt* an additional support which would not only compensate for any present pecuniary loss, but prove ultimately greatly to its financial advantage. The opinion appears to be nearly unanimous among botanists consulted by the Committee, that it would be far better that the *Centralblatt* should be modified to meet what appear to be but reasonable requirements in a journal devoted primarily to reviews than that a new journal should be started, and that the starting of a new journal should be resorted to only after every effort has been made to secure the desired reforms in the *Centralblatt*.

Under these circumstances the committee ventures to hope that the editors and publishers of the *Centralblatt* will take these matters again into consideration, and may be able to return a reply that will be proved a solution of all present difficulties.

To this letter, Dr. Uhlworm replied as follows:

After mature consideration of your propositions, in regard to the justice of which we have had no objections from the beginning, we have come to the conclusion to publish nothing but *Referate* and *Neue Litteratur* in the regular series of the *Botanisches Centralblatt*, which is to be of the same size and price as heretofore, and which can, of course, be subscribed for by itself. The *Beihefte*, however, which appear from time to time and may likewise be subscribed for alone, would then contain the orginal articles. In regard to the financial support of the American botanists, concerning which we had spoken only because we had concluded from your first communication that you proposed a considerable increase in the size of the *Centralblatt*, we shall of course say nothing more under the existing circumstances. We should feel deeply grateful, however, if your Committee, and especially the two gentlemen whom you select as associate editors, would give us your, support by an active cooperation, and would bring the *Centralblatt* to wider notice in America. * * * Above all things, I am naturally desirous of presenting the new American literature as rapidly and completely as possible to our readers in the future. In this connection, however, I must ask for support from you to the extent that you cause the American authors, institutions, societies and periodicals to send me a copy of newly published articles as quickly as possible for publication in *Neue Litteratur*. Written titles conduce, as I know from years of experience as a librarian and editor, only to unfortunate errors and to confusion.

It is to be hoped that a union of the American and European botanists will result in a real advance in the *Centralblatt*. I shall do all in my power to bring this about. I shall do my best to make this

joint work a most successful undertaking. I hope that I shall succeed in making similar arrangements with the botanists of other countries.

The report comments upon the foregoing as follows:

The committee feels that the Society is greatly indebted to the editors of the *Centralblatt* for their courteous letter and must be highly gratified with their statement of the changes which they express themselves prepared to make in the near future. The changes, as will be seen from Dr. Uhlworm's letter, are in conformity with the suggestions made by the committee in its report and will meet with the approval of all American botanists. It is proposed to include in the *Centralblatt* proper, only reviews and the index of literature; the *Beihefte* will contain only original articles; the *Centralblatt* may be subscribed for without also subscribing for the *Beihefte*, and, lastly, the price of the *Centralblatt* is to remain as at present. On these points, therefore, the letter of Dr. Uhlworm is entirely satisfactory.

The suggestions that American editors be nominated by a representative body of American botanists seem to be excellent and likely to prove helpful to the *Centralblatt* by stimulating our botanists to make a determined and combined effort to do all in their power to enable the editors of the *Centralblatt*, so far, at least, as American botanical literature is concerned, to make their journal indispensable to all botanists. Hereafter, it will be a matter of pride to us to show that our interest is not merely passive, but that we are ready to make active individual and collective effort to secure a desirable result.

The Committee closes its report with the following recommendations:

First, that the Secretary be directed to write to Dr. Uhlworm and express our hearty approval of the changes proposed, and our readiness to cooperate.

Secondly, that a committee of three be appointed by the Society with full power to represent the Society in further negotiations with the management of the *Centralblatt* up to such time as the selection of American editors shall have been definitely made, the committee to report to the Society at its next annual meeting.

Thirdly, that the committee thus appointed be requested to invite one botanist from the Central States and one botanist resident on the Pacific Coast to serve with them in the selection of American editors, and in such preliminary business as may be necessary for the furtherance of the plans proposed by the editors of the *Centralblatt*.

Fourthly, that a copy of this report, or of such parts of it as may seem desirable in order to call the attention of our botanists to the changes to be made in the *Centralblatt*, be sent to the *Botanical Gazette*, the *Bulletin of the Torrey Club* and to SCIENCE.

In accordance with the second recommendation, Messers. Farlow, MacDougal and Ganong were appointed upon the new committee to carry out the work to completion, and Messrs. Trelease and Campbell have since been added, in accordance with section three above. The botanists of the country are to be congratulated upon the results achieved by these negotiations. The changes proposed, and in part already put into effect, promise to make the *Botanisches Centralblatt* an efficient and economical journal of reviews indispensable to every working botanist. It is hoped that those of America will manifest their appreciation of its advantages, and their acknowledgment of the efforts of its editors and publishers to meet their wishes, by a cordial and practical support. Upon this latter subject a further communication is expected from the Committee. CHARLES E. BESSEY.

SCIENTIFIC BOOKS.

Proceedings of the Society for the Promotion of Engineering Education. Vol. VIII. 1900. Edited by PROFESSORS JOHNSON, KINGSBURY and JACOBY. New York, Engineering News Publishing Co. 1900. 8vo. Pp. 377.

It may be doubted whether, in any other department of applied science, a larger, a more important, or a more fruitful work is being done than in the field occupied by the Society of which the transactions are here recorded. The members of the Society are engaged in the technical schools and colleges of the country in the professional training of men who are to hereafter lead in the application of the discoveries of science, of the inventions of the useful arts and of the methods of modern industrial operation in the new century. Their work is the instruction of youth who, having completed the general education that their parents' money and their own time and scholarly proclivities may afford them, turn their attention to the

scientific principles which are the recognized foundation of their professional work and the basis of professional success. The work is that which has brought Germany up from insignificance, industrially, and made her one of the world's most important producers, placing her people in the foremost rank in all applied sciences and in all arts based upon science. Their opportunities are greater than those of their German colleagues; they recognize the facts and are evidently seeking to make the most of them. The record is rich in instructive and suggestive matter.

The earlier pages of the volume are given to the lists of officers, council, committees and members. The last number already—the Society was organized at the World's Congress at Chicago in 1893—nearly 300, of whom New York and Massachusetts claim 29 each; Ohio, 20; Pennsylvania, 18; Indiana and Illinois, each 15; Michigan, 13; Minnesota, 12, and other States smaller numbers; 36 States being represented, one Territory, and also Canada, England, France, Germany, Switzerland and Australia, mainly single representatives, although Canada has six. Any one occupying, or who has occupied, a position as a teacher in any branch of work in the engineering school or college is eligible to membership. The conventions occur annually and usually in conjunction, as to time and place, with the American Association for the Advancement of Science. The finances of the Society seem to be in admirable shape.

The proceedings for the year 1900 include an address by the President on the work of the nineteenth century in this field, the report of the committee appointed to answer the question, regarding industrial education generally: 'What shall it be?' an abstract of which has already been given in these columns, and a total of about twenty papers and reports of committees of a most valuable and interesting character. Those on the form of the industrial educational system, on 'Personality in Teaching' and on 'Business Methods in Teaching Engineering,' gave rise to earnest and helpful discussions of very general interest; as did, also, the two papers, coupled together, on the 'Present Status and Tendencies of Engineering Education in the United States' and on 'The Promotion of Engineering Education.' The last two papers on the list, one on 'The Modern Mechanical Laboratory,' presented simultaneously, also, to the Paris Congress on Applied Mechanics, and the other on 'Operating Work as a Feature of Electrical Laboratory Training,' were received too late for discussion.

Of these papers, the report first alluded to above, already noticed in these columns, is here printed, with a discussion of great extent and exceeding interest and in some respects perhaps more valuable than the report which provoked it. The report of the committee is strongly endorsed, and the speakers, including some of the ablest in the field, present a great variety of new views and of crucial problems such as must long afford food for thought to all interested in this subject. And what intelligent citizen is not thus interested? Heads of engineering and technical schools, practitioners, famed and expert, teachers, distinguished and likely to become distinguished, and every department of technical instruction and practise give testimony. The paper on 'Secondnry Technical Education' and those on details of work may be taken to be extensions of this discussion; and most helpful they are likely to prove to all who are either directly or indirectly concerned in this most important to the industrial community of all modern departments of applied science.

R. H. THURSTON.

Kant's Cosmogony. Edited and Translated by W. HASTIE, D.D., Professor of Divinity in the University of Glasgow. New York, The Macmillan Co. 1900. Cr. 8vo. Pp. cix + 205. Price, $1.90.

This is an excellent bit of work, not only admirable in the scholarship and learning that go to its execution, but noteworthy in its timeliness as a contribution to English 'Kant philology.' So far as the editor is concerned, the book means that the days of heat and partisanship about the critical philosophy are past, that a man dare call attention to Kant's place in scientific evolution and yet keep a whole skin. No doubt there are those who will squirm uncomfortably when they read; Kant's 'Natural

History and Theory of the Heavens,' as he ultimately designated its exposition, will probably be regarded hereafter as the most wonderful and enduring product of his genius" (Introduction i); and will write Dr. Hastie down a philosophical Dogberry. "It is a charming incongruity to find, while Leonato rages and Benedick offers his challenge, that Dogberry is the one to unravel the tangle of threads." Our editor, untrammeled by the faction of recent schools, sees more clearly than those who, distraught by preconceived opinion, have dealt us our Kant *schillernd*. In view of their battles, it may be added that the 'Natural History' possesses this chance of future fame—it can be understood.

Some of Dr. Hastie's friends may be inclined to regret that he has elected to enlist his uncommon erudition, strong personality and vital enthusiasm in the work of making other authors known, rather than in the production of original books. This regret is mitigated, in the present case, by the fascinating 'Introduction,' which is a real addition to our literature on Kant. Indeed, Dr. Hastie has done much more than 'edit and translate,' as the modest legend runs on the title page, and the result is a highly composite production, the contents of which it were well, therefore, to set forth in detail. The book falls into three distinct portions. *First*, comes the 'Translator's Introduction,' extending to 101 pages, and divided into eight sections, as follows: (1) 'Relation of Kant's Science to his Philosophy'; (2) 'the Scientific Return to Kant'; (3) 'Kant's Scientific Environment and Antecedents'; (4) 'Kant's Discovery of the Retardation of the Rotation of the Earth'; (5) 'Kant's Natural History and Theory of the Heavens'; (6) 'Kant's Cosmogony in its Historical Relations'; (7) 'Kant's Cosmogony in Relation to Religion and Theology'; (8) 'Kant's Scientific Achievement Generally.' The appropriateness of the dedication of the book to Lord Kelvin becomes apparent on this recital. *Second*, the main body of the work, presenting (1) a translation of Kant's essay on the question (proposed by the Royal Academy of Sciences at Berlin), 'Whether the Earth has undergone an Alteration of its Axial Rotation' (1754); (2) a translation of Kant's 'Universal Natural History and Theory of the Heavens; or an Essay on the Constitution and Mechanical Origin of the Whole Universe, treated according to Newton's Principles' (1755). These translations fill 167 pages. *Third*, the Appendices, giving (1) a translation of Konrad Dieterich's 'Summary of Kant's Theory of the Heavens,' taken from his 'Kant und Newton' (1876); (2) a translation of the 'Hamburg Account of the Theory of Thomas Wright of Durham,' taken from the MS. in the library of the university of Edinburgh. This MS. is an excerpt copy transcribed from the 'Freye Urtheile und Nachrichten zum Aufnehmen der Wissenschaften,' a periodical published at Hamburg. The Wright account came in the first number of the eighth year (January, 1751). Wright's work, there summarized, was entitled, "An Original Theory or New Hypothesis of the Universe, Founded upon the Laws of Nature, and solving by Mathematical Principles the General Phenomena of the Visible Creation; and particularly the *Via Lactea*. Comprised in Nine Familiar Letters from the Author to his Friend. And illustrated with upwards of thirty graven and mezzo-tinted Plates by the best Masters. London, MDCCL." This portion is embellished with a protrait of Wright. (3) A reprint of 'De Morgan's Account of the Speculations of Thomas Wright of Durham.' This is taken from the 'London, Edinburgh and Dublin Philosophical Magazine and Journal of Science,' volume xxxii (1848). These appendices fill 38 pages.

By merely glancing over these titles, any one can infer that, if the labor involved be well done, the book constitutes a most valuable contribution to a chapter in the history of the relation between science and philosophy. As I have already said, Dr. Hastie's part is admirably sustained. Indeed, I would have scientific men, in particular, read the book carefully, for it must act as a powerful solvent upon certain unfortunate prejudices.

A word, in passing, about Wright. Like many another, so unfortunate as to live ere the times were ripe, he has been consigned to unmerited oblivion. Even the writer of the entry upon him in the 'Dictionary of National Biography'—a work so uniformly accurate—is un-

aware of the sources from which information could have been obtained, and so has nothing to tell,—does not even know the dates of his birth and death, or why he was called 'of Durham.' Wright was born at Byer's Green, near Durham, in 1711, and died there in 1786. Brought up as a 'philosophical instrument-maker,' his attention was called early to mathematico-physical problems and, by his thirty-first year, he had gained such reputation as a teacher of mathematics (like other eminent English scientists, a *private* teacher) that he was called to the chair of navigation by the Imperial Academy of St. Petersburg, an offer which he did not accept. There would seem to be no reasonable doubt that he was the first to light upon the modern physico-philosophical theory of the material universe. As De Morgan says, 'He gave the theory of the milky way which is now considered as established,' and he predicted 'the ultimate resolution of the rings of Saturn into congeries of small satellites' (203). The conclusion of Wright's seventh letter furnishes a striking instance of his remarkable prevision. "Thus, Sir, you have had my full opinion, without the least reserve, concerning the visible creation, considered as part of the finite universe; how far I have succeeded in my designed solution of the *Via Lactea*, upon which the theory of the whole is formed, is a thing will hardly be known in the present century, as in all probability it may require some ages of observation to discover the truth of it" (202). The 'ages of observation' and the Lick Observatory have not failed him. An edition of the 'Original Theory' was published in this country, at Philadelphia, by Rafinesque (1837). If Dr. Hastie had done no more than rescue this man's name from blank oblivion, he had deserved well of students of science. And he has accomplished much besides.

Apart altogether from its contribution to our knowledge of the manner in which Kant's early scientific studies influenced his later philosophical speculation—a contribution by no means inconsiderable as our somewhat scanty literature in English goes, the book ought to have distinct effect in bringing us to a clear consciousness of the close and friendly relations between science and philosophy maintained from the days of Bacon, Galileo and Descartes till broken off, during the estrangement between the German idealists and modern scientific men, since 1840. This is a long story, upon which I can not enter now. Further, it happens to have been misunderstood or forgotten till within the last few years. An earnest of better things appears to some at least to be one of the most interesting features of contemporary tendencies. To build this promise into actual fact, we need just such books as this. And, accordingly, Dr. Hastie has fairly won our warmest thanks. It is one of his greatest merits that he stands clear from all scientific and philosophical controversies, and so can state what he knows in its definite bearings, not in those which he might desire it to assume.

There must be some good hope for the future of Scottish theology when, at the university which has recently lost from its staff the most eminent living British physicist and the greatest living British Kantian scholar, the chief chair of the divinity faculty is ornamented by the occupancy of a thinker so successful in appreciative unification of the sundered learning of his famous colleagues.

R. M. Wenley.

University of Michigan.

A School Chemistry. Intended for use in High Schools and in Elementary Classes in Colleges. By John Waddell, B.A. (Dal. Coll.), B.Sc. (Lond.), Ph.D. (Heidelberg), D.Sc. (Edin.). Member of the American Chemical Society; formerly Assistant to the Professor of Chemistry in Edinburgh University; Lecturer in Chemistry in the School of Mining, Kingston.

So far as the general method of arrangement and treatment is concerned, this book is similar to others intended for the same purpose; but there are several points to which attention might be called. The author has avoided the error so often made of subordinating facts to theories, and says in the preface: "The endeavor is made in this book to help the pupil in the discovery of new facts, to enable him to see their connections, and to show how facts lead to theory and theory aids in investigation

and in the discovery of further facts. The subject is presented in what seems to me the correct perspective, theory being subordinated to fact." The method of treatment is the interrogatory one and an effort is made to teach the student to observe for himself. While this method is an excellent one in theory it is doubtful whether it can be used with success with a class of beginners who have had no experience in scientific methods. In the early stages of the work they must be taught how to observe, and their powers of observation must be trained by showing them what they should see in each case. In some cases the important features of the experiment might be entirely overlooked and unimportant details magnified if the attention is not directed to the desired points. Of course, this might be overcome by constant personal contact with the student; but such is hardly possible in many institutions.

SCIENTIFIC JOURNALS AND ARTICLES.

IN the January number of the *Physical Review* Theodore Lyman presents the results of a study of the 'false spectra' often produced by a Rowland concave grating. These spectra are most clearly seen in the extreme ultra-violet, and are shown to be diffraction spectra of much less dispersion than the ordinary spectra. They appear to be due to errors of ruling, extending over the whole surface of the grating. A. A. Noyes describes in the same number a modification of the usual method of determining transference numbers, and applies the method to a large number of salt solutions of varying concentration. The application of interference methods to the determination of Poisson's ratio forms the subject of an article by J. R. Benton; while two articles by Chas. T. Knipp deal respectively with the employment of the bicyle wheel in illustrating the principles of the gyroscope, and with a new form of automatic temperature regulator. The former article describes a number of simple experiments with an ordinary bicycle wheel which are readily performed, and at the same time illustrate very strikingly the properties of the gyroscope and gyroscopic pendulum. Experiments are described by E. C. Roberts to determine whether the dielectric constant is altered by a magnetic field. The results are wholly negative.

THE January number of the *American Journal of Mathematics* (Vol. XXIII., No. 1), contains the following articles: 'Die Typen der linearen Complexe rationalen Curven im R_r,' by S. Kantor; 'Transformation of Systems of Linear Differential Equations,' by E. J. Wilczynski; 'Distribution of the Ternary Linear Homogeneous Substitutions in a Galois Field into Complete Sets of Conjugate Substitutions,' by L. E. Dickson; 'Distribution of the Quaternary Linear Homogenous Substitutions in a Galois Field into Complete Sets of Conjugate Substitutions,' by T. M. Putnam; 'On the Determination and Solution of the Metacyclic Quintic Equation with Rational Coefficients,' by J. C. Glashan; 'Construction of the Geometry of Euclidean n-Dimensional Space by the Theory of Continuous Groups,' by E. O. Lovett; 'A Table of Class Numbers for Cubic Number

Fields,' by L. W. Reid; 'On Certain Properties of the Plane Cubic Curve in Relation to the Circular Points at Infinity,' by R. A. Roberts. The number contains a portrait of the venerable ex-mathematician, George Salmon, Provost of Trinity College, Dublin.

The Popular Science Monthly for February has for its leading article 'Huxley's Life and Work,' by Lord Avebury, being the first Huxley Memorial Lecture of the Anthropological Institute of Great Britain. 'Malaria,' by Geo. M. Sternberg, being the address of the President of the Philosophical Society of Washington, gives a *résumé* of our knowledge of this subject and brings it up to date. 'A Study of British Genius,' by Havelock Ellis, is based on the Dictionary of National Biography and this, the introductory paper of a series, explains how the selections were made and gives the names of those selected. 'The Weather *vs.* the Newspapers,' by Harvey Maitland Watts, is an excellent brief exposition of the main facts of weather phenomena and of the general misunderstanding by the press and public. A brief and interesting article on 'The Philippines Two Hundred Years Ago,' by E. E. Slosson, is culled from the writings of Father Dominick Fernandez Navarette and Dr. John Francis Gemilli Careri. 'The Prehistoric Tombs of Algeria' are described by Alpheus S. Packard. Charles L. Bristol treats of 'The York Aquarium,' and in 'Chapters on the Stars,' Simon Newcomb discusses their clustering, the Milky Way, and stars with waning brightness. Finally Oliver C. Farrington, in 'A Century of the Study of Meteorites,' gives a brief summary of our knowledge of these bodies. Discussion and Correspondence comprises two contributions that especially deserve to be read, the one 'A Defense of Christian Science' as a fine example of this peculiar style of 'scientific' writing; the other 'Mr. Tesla's Science,' for its temperate criticism of certain kinds of 'science.' The departments of 'Scientific Literature and the Progress of Science' contain much good reading.

Bird Lore for February opens with an article on 'Pelican Island Revisited,' by Frank M. Chapman, with numerous and admirable illustrations from photographs by the author. 'Elliott Coues on Audubon' is a verbatim report of an address delivered by Dr. Coues before the American Ornithologists' Union in 1897, and this is followed by "Three Letters to Audubon's 'Kentucky Lads'" (his sons Victor and John), contributed by Maria R. Audubon. 'An Adirondack Lunch Counter,' with illustrations, describes the habits of some of the winter visitors. The second series of 'Birds and Seasons' discusses the birds to be met during February and March in various sections of the country, and then comes 'The Christmas Bird Census,' giving a list of the birds noted on that day at various places from Massachusetts to California and Canada to Louisiana. There is an interesting paper, by C. William Bebee, of a pair of Bald Eagles in the New York Zoo, who built a nest and have placed therein a good-sized stone on which they sit. Reviews and the department devoted to the Audubon Societies complete the number.

The Vermonter, St. Albans, Vt., C. S. Forbes, publisher, begins the year in magazine form and proposes to print monthly articles on the history, science and mineral interests of Vermont. The February number contains an interesting article on the geology of Vermont by Professor Henry M. Seely, of Middleburg College.

THE University of Missouri is about to publish, under the editorship of Frank Thilly, professor of philosophy, a series of *University Studies*, containing contributions by members of the faculty and graduate students.

SOCIETIES AND ACADEMIES.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

AT the 529th meeting held February 2, 1901, three reports were made of observations during the solar eclipse of May 28, 1900.

Professor S. P. Langley reported on the Smithsonian observations at Wadesboro, N. C., exhibiting many lantern slides of the apparatus used and superb photographs of the corona and sky. He stated that direct photographs were taken showing the moon 15 inches in diameter, and that the bolometric work, performed by Mr. Abbot, showed the heat from the corona to be only five eighty-fifths of that received from

the full moon. He dealt particularly with the interest that attached to further photography of the region of the sun independently of the corona, and pointed out that with a wider shadow track, such as might be expected in Sumatra in next May, there was reason to expect that stars as small as the ninth magnitude might be secured; and he showed that on a reasonable supposition as to brilliancy the diameter of such a body might be supposed to be something like the one one-hundredth part of that of Mercury, or in a rough way, one-tenth of a second on the solar disk. The observers were aided of course by irradiation in seeing this as a star, while on the surface of the sun he could say from a good deal of experience that such a body would be invisible.

The argument against the existence of a zone of such small bodies, from their never having been seen on the sun's face, was therefore inconclusive. He did not himself look forward with confidence to any new discovery being made in this direction, but he was encouraged by the opinion of a very competent adviser to think that the observation was worth repeating under better conditions. It was also desirable to repeat and extend the observations on the heat of the inner corona made at the late eclipse, and he had decided to send out a very small expedition to Sumatra in the immediate charge of Mr. C. G. Abbot, of the Smithsonian Astrophysical Observatory. The ultimate station in the interior of the island has not yet been determined.

Professor S. J. Brown, of the Naval Observatory, showed slides from some of the photographs taken by his party in North Carolina, those of the flash spectrum being specially interesting, and other slides from Mr. Burckhalter's photographs in which the outer portions of the corona had a progressively longer exposure than the inner parts.

Dr. L. A. Bauer reported on 'The Coast and Geodetic Survey, Magnetic Observations During the Late Eclipse.' Records from several stations within and without the belt of totality showed that at all of them the regular morning change of declination was interrupted very nearly at the time of totality and reversed in direction for half an hour to an hour, the average magnitude of the reversed movement being about 30 seconds, while the probable error of a reading is not over 3 seconds. At one station the intensity was observed, and here a similar reversal of the regular change was noted, amounting to three times the probable error of a reading, the intensity being diminished. No satisfactory explanation has yet been given of these reversals.

CHARLES K. WEAD,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 333d meeting was held on Saturday evening, January 26th, and was devoted to a discussion of the question of 'Former Land Connections between Asia and North America.' In introducing the subject F. A. Lucas said the questions to be considered were the existence and probable geologic time of such connections and their place, whether by way of the Aleutian Islands or across Bering Strait. The distribution of the North American sheep and brown bears, the presence of abundant and comparatively fresh remains of the northern mammoth, *Elephas primigenius* in the northwest, and the fact that the remains of a bison, *B. crassicornis*, were found in Alaska only pointed to a rather recent and brief land connection. Hints of a much earlier land connection were shown by the existence of a fossil *Nemorhedus* in Colorado and by the occurrence of the southern mammoth, *Elephas columbi*, from Oregon southwards and eastwards.

Theo. Gill said that the fossils and recent mammals pointed to a recent brief connection between the continents, but that a more ancient one was indicated by the distribution of certain fresh-water fishes. The pike, *Lucius lucius*, was common to Europe, Asia and America and the nearest allies of the American *Polyodon* and *Scaphirhynchus* were *Psephurus* and several relatives of *Scaphirhynchus* found in Asia. These fishes were of old types, while the existing Cyprinoid fishes so characteristic of the streams of North America did not occur in Asia.

W. H. Dall discussed the geology of the contiguous portions of Asia and North America, and described the hydrographic and climatic conditions existing in Bering Sea, saying that

owing to the depth of water and configuration of the bottom between the western Aleutian Islands and Asia no land connection could have taken place there. That even man could have crossed at this point on the ice was also out of the question, as the pack ice rarely reached even the easternmost islands of the chain. The speaker spoke of the conditions under which the excrement of the Mammoth was found in the body of land ice about Kotzebue Sound, as this showed that the animal actually traveled over the ice now in place. The water of Bering Strait was stated to be so shallow that it might readily have been filled with ice during the glacial period, and the Mammoth might have crossed over this ice bridge.

F. V. Coville discussed the character and distribution of the vegetation of the adjacent regions, stating that the absence of trees, common to the adjacent portions of Asia and North America, showed that there could have been no recent land communication of any long duration. The smaller plants pointed to a brief recent union of the continents.

L. Stejneger said that the genus *Alligator* of the southern United States also occurred in Asia, and the nearest relatives of the hellbender, *Cryptobranchus*, of the eastern United States were the giant salamanders of Japan and western Asia, and that these facts indicate an old land connection of long duration. The existence of a circumpolar fauna, which had been lightly treated by previous speakers, also appeared to Dr. Stejneger to corroborate the evidence of the reptiles and batrachians.

F. A. Lucas.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

The 312th meeting was held on January 29th.

Dr. George M. Kober exhibited an antique German clock which he collected in Hesse Darmstadt. This clock, though only 125 years old, is closely patterned after the clock of Henry de Wyck (1364).

W J McGee gave an interesting account of his explorations in Sonora, Mexico, and in Southern Arizona. The search for the Tepoca Indians, relatives of the Seri, which was the principal object of the expedition, proved futile, the Tepocas recently having disappeared from their former location. Mr. McGee also visited the Cocopas living on the tide flats near the mouth of the Colorado in an isolated locality. It was observed that the Cocopas are not fishermen, though their situation offers great advantages for that pursuit. They practise agriculture in a primitive manner and make use of few introduced plants. These Indians are declining rapidly in number, the chief cause stated by Mr. McGee being the adoption of European clothing. Mr. McGee during this expedition found along the Colorado a new method of picture writing, pebbles having been removed from an even gravelly surface to form various designs.

Owing to the illness of the President, Professor W. H. Holmes, the exhibition and unwrapping of a Peruvian mummy by Professor Holmes and Walter Hough was postponed.

Major Powell's important paper on 'Philology' occupied the greater part of the evening and was discussed by Albert S. Gatschet and Alice C. Fletcher. The paper is the fourth of a series of five on Demonomy, or human activities. Major Powell in a closely reasoned paper treated of language under the heads of emotional language, oral language, gesture language, written language and logistic language. His treatment of emotional language was especially attractive. He insisted that languages were formerly more numerous than now, the tendency being toward coalescence.

At the close of the paper the discussion was participated in by P. B. Pierce, Rev. Henry M. Baum, J. H. McCormick and W J McGee.

Walter Hough.

CHEMICAL SOCIETY OF WASHINGTON.

The regular meeting was held on January 10, 1901. The following officers were elected for the ensuing year: *President*, Mr. V. K. Chestnut; *Vice-Presidents*, Dr. W. F. Hillebrand, Dr. F. K. Cameron; *Secretary*, Mr. L. S. Munson; *Treasurer*, Mr. F. P. Dewey; *Additional Members of the Executive Committee*, Dr. H. N. Stokes, Dr. H. C. Bolton, Mr. E. E. Ewell, Mr. L. M. Tolman.

William H. Krug,
Secretary.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

A REGULAR meeting of the Section was held on January 28th. A paper on 'Certain Racial Characteristics of the Base of the Skull' was presented by Dr. A. Hrdlicka. The paper dealt with the middle lacerated foramen, the petrous portions of the temporal bones and the styloid. The author demonstrated the different stages of development of these parts in primates and at different stages of life in the whites, and the differences of those parts, fully developed, in the negroes, Indians and whites. In the adult whites the average middle lacerated foramen is large, the petrous portions appear considerably sunken (bulging of surrounding parts), the styloid is well developed. In the Indian the foramen is but a moderate size, in negro small, in apes absent; the petrous portions are less sunken in the Indian than in the white, on, or almost on, the level with the surrounding parts in the negro, bulging more or less beyond these in the primates; the styloid is in the majority of cases small in the negro and small to rudimentary in most of the Indians. Where the styloid is rudimentary, the vaginal process often plays a compensatory part. In whites all the mentioned stages of the parts described may be observed at different periods of life. Brain development accounts for the differences in the size of the middle lacerated foramen and the relative position of the petrous portions.

The second paper was on 'The Alsea Indians of Oregon' and was read by Dr. Livingston Farrand. The paper reported observations made by the author on the language customs and traditions of this tribe.

CHARLES H. JUDD,
Secretary.

DISCUSSION AND CORRESPONDENCE.

FREE SPEECH IN UNIVERSITIES

RECENT events in certain American universities have again raised the old question as to the right of the professor to freedom of speech. Sensational reports in the newspapers have loosened floods of sympathy for the alleged victims of tyranny, and the popular belief is that great wrong has been done. Whether this belief is correct or not, few men are in a position to know, for the complete evidence has not been made public, and in default of that no reasonable criticism is possible. But a discussion of the principles involved in such cases is in order, and, indeed, it seems to be most necessary.

That a university professor should be free to teach his honest convictions would seem at first sight to be a most reasonable proposition. But the rights of the teacher are not absolute; they are limited by the rights of the pupils and the rights of the institution in which he is employed. The institution must protect its own dignity and reputation; the student is entitled to protection against obvious error and against the wastage of his time; and to these rights the rights of the professor are subordinate.

Suppose for example that a professor of mechanics should spend his time in teaching his class the possibility of perpetual motion. Or that the professor of mathematics should try to demonstrate in the class-room the squaring of the circle. Or that the professor of astronomy should denounce the heliocentric theory of the solar system and adopt the mediæval teachings of Cosmas Indicopleustes. His right to freedom of teaching would avail him little, and he would be promptly invited to resign his position. The right of the professor to teach is conditioned by the right of the pupil to learn, and the latter right is entitled to first consideration. The teacher has no right to teach nonsense nor to waste the time of his students over his own personal vagaries. Irresponsible freedom of speech or of teaching is plainly inadmissible; a point which certain sentimentalists have failed to see.

The present controversy, however, has not dealt with obvious questions of truth or error, but with subjects which are still under discussion and unsettled. In sociology and economics we find the chief difficulties, and here the rights of the professor are not quite so clear. Still, the responsibility on his part remains, and it cannot be honestly evaded. If a professor of sociology, speaking in his class-room, should denounce the present institution of marriage

and advocate either polygamy or free love, his honesty of purpose, his right to teach his views, would not protect him from dismissal. This is an extreme case, a case not likely to arise, but it serves to illustrate the principles at issue. All the rights of the professor are governed by reasonable limitations.

Unfortunately, at the present time, the leading economic and social questions are partly political in their nature. Their public discussion is almost wholly partisan, rarely scientific, and violent passions are easily aroused. The tariff, the coinage, the question of the so-called trusts are all alive in the public mind, and the professor of economics therefore stands on very precarious ground. What are his rights and his duties now? They are still limited, and his responsibilities are greater than ever.

Whatever a teacher may be in his private life, his personal bias is to be put under strict control the moment he enters his lecture room. There the partisan is out of place, and the interests of science rule. The professor now should cease to be an advocate, seeking to win converts, and become the equivalent of a judge who sums up the case before a jury. He must be fair, judicial, tactful and dignified; and failure in any one of these particulars is a serious limit to his usefulness. He may believe in free trade, but he should give the evidence and arguments upon both sides of the question. If he neglects to do this he defrauds the students of their rights and is a failure as a scientific teacher. He need not efface himself, he need not suppress his preferences, but he must be fair and thorough. The pupil can not understand an economic controversy without hearing both sides, and his rights in this respect are entitled to consideration. The class-room is no place for political tirades, nor for partisan denunciation, either of institutions or of individuals; it should be sacred to honest scientific discussion, regardless of parties or persons. A want of tact upon the part of the teacher, a lack of dignity in his treatment of a doubtful question, may easily become a source of trouble and justly lead to his dismissal.

That some teachers may have been unfairly treated I will not deny, for in the conflict of rights it is sometimes difficult to strike an even balance. What I have said applies to general principles, not to any special, concrete cases. Each case stands upon its individual merits, which are rarely known except to the parties who are immediately affected. The principles, however, are clear, and should be borne in mind whenever the management of a university is criticized. The latter may be in the right, despite appearances; and it is quite conceivable that a teacher may be in the wrong.

F. W. Clarke.

SHORTER ARTICLES.

THE RELATION OF SEEDINESS TO QUALITY IN MELONS.

In the *Memoirs of the Torrey Botanical Club*, Vol. 1, No. 4, issued May 30, 1890, the late Dr. E. Lewis Sturtevant contributed an article on 'Seedless Fruits' in which he presented a large amount of data compiled from various sources relative to seedless fruits as correlated with quality. Some of his statements I quote as follows: "There seems to exist in fruits a correlation between seedlessness and quality, especially when that quality is expressed by the term tenderness of tissue." "The better varieties of the apple usually contain some abortive seeds, and are sometimes individually to be found seedless. As a rule, where there is a tendency to abortive seeds, the larger and finer the apple the greater the number of abortive seeds." "Melons of the highest quality contain fewer seed than do varieties of medium or inferior quality, as I have often observed. This even seems to hold true as between individual fruits of the same variety to a marked extent."

In the autumn of 1893, my assistant, Mr. Cranefield, made a study of thirty-five muskmelons to ascertain to what extent Dr. Sturtevant's conclusions would be verified. The data have been preserved, but the results have not before been published.

These melons were the result of a cross between the Algiers cantaloupe and several American varieties. The fruits were picked when the stem readily detached, and weighed on a torsion balance that is sensitive to the

tenth of a gram. They were then cut into halves and the seeds were taken out and weighed with the adhering pulp, after which the seeds were removed from the pulp, wiped as dry as possible on a towel and weighed. The percentage of seeds was computed by dividing the weight of the seeds by the weight of the melon. The diameter of the melon was then measured, also the thickness of the flesh and of the rind. The flesh was then tested for firmness, texture and flavor. The flavor was rated on the scale of five as best.

In five melons rated poorest in flavor, the weight of the seeds averaged 1.636 per cent. of that of the melon; in five rated of best quality, the weight of the seeds averaged 1.34 per cent. of that of the melon.

In five melons of 'coarse' texture, the weight of the seeds averaged 1.764 per cent. of that of the melon; in five of 'fine' texture, the weight of seeds averaged 1.364 per cent. of that of the melon.

In five melons having the thickest flesh, the weight of the seeds averaged 1.53 per cent. of that of the melon; in five having the thinnest flesh, the weight of seeds averaged 1.54 per cent. of that of the melon.

In five of the heaviest melons, the weight of the seeds averaged 1.34 per cent. of that of the melon; in five of the lightest, the weight of the seeds averaged 1.684 per cent. of that of the melon.

It appears that so far as texture of flesh and flavor are concerned, Dr. Sturtevant's conclusions were verified.

E. S. GOFF.

WISCONSIN AGRICULTURAL EXPERIMENT STATION.

PREDETERMINED EVOLUTION.

THE American Redstart (*Setophaga ruticilla*) is structurally very widely separated from the true Redstart (*Ruticilla phœnicurus*) of Europe, and yet outwardly resembles it to an extraordinary degree. This fact has caused Professor Alfred Newton (*Ency. Brit.*, XX., 318) to write as follows: "The wonderful likeness, coupled of course with many sharp distinctions, upon which it would be impossible to dwell, between the birds of these two genera of perfectly distinct origin, is a matter that must compel every evolutionist to admit that we are as yet very far from penetrating the action of creative power, and that especially we are wholly ignorant of the causes which in some instances produced analogy."

Cases of this sort may excite our wonder, but they are much more common than is often realized. In New Mexico and Arizona we have a series of numerous species of snails, which possess shells in no way distinguishable, except in a specific sense, from those of the genus *Polygyra*, which is dominant in the eastern States. During the last two years the anatomy of several of these species has become known, and it turns out that they are not even closely allied to *Polygyra*, but represent a peculiar genus which has been named *Ashmunella* (Pilsbry and Cockerell). In Arizona and southern New Mexico there is another series of snails, which has nearly the shell of *Epiphragmophora*, a genus of the Pacific coast. The species were always referred to the last-mentioned genus until Professor Pilsbry recently dissected one of them, *E. hachitana* of Dall. It then appeared that we had here another perfectly distinct genus, which was named *Sonorella* (Pilsbry). But not only do these interesting resemblances occur between species of our continent; they are seen equally between species of different continents. Some of the California species of *Epiphragmophora* so closely resemble the European *Arionta* that naturalists were for a long time deceived. I have recently had occasion to notice the extraordinary resemblance between certain Japanese snails and those of the United States. Thus, *Eulota connivens* (Pfr.) of Japan might easily be taken for *Sonorella hachitana* of Arizona; and *Eulota mercatoria* (Gray) is remarkably similar to *Epiphragmophora fidelis* (Gray), the first being from Japan, the second from Oregon.

Is it possible that we may find a real, if imperfect, parallel between this independent development of similar species and the development of diverse cells in the metazoa? A human being, for instance, contains innumerable cells of very diverse nature, all descended directly from the ovum or germ-cell. If these cells were not parts of an organic whole, but lived separate lives, we should speak of their descent

from a primitive common ancestor (the germ-cell) and their evolution in the course of countless generations into distinct genera and species. Coues, in fact, has gone so far, in writing of bird-anatomy, as to treat the different kinds of cells as pertaining to several genera and species, which he names.

But we are here met by the extraordinary fact that all this complicated development and evolution is repeated anew in every individual, and that, speaking broadly, the course of cellular evolution is predetermined in the germ. This fact is so commonplace to us that we have ceased to realize the wonder of it, or its possible significance as a hint of the method of evolution among species.

Why may it not be that the evolution of species, to a greater or less extent, is similarly predetermined, and that here is to be found the explanation of the phenomena described in the beginning of this note? If life exists in Mars, a knowledge of it would go far toward answering such a question. How much similarity would there be between creatures evolved on two planets, with all the diversity of conditions which this implies?

T. D. A. Cockerell.

East Las Vegas, N. M.,
January 29, 1901.

NOTES ON PHYSICS.

NON-PERMANENCE OF WEIGHT.

Experiments by Heydweiller (*Phys. Zeitschr.* Aug. 25, 1900), similar to those of Landolt (*Zeit. für Phys. Chem.*, 12, p. 1, 1893), seem to show that a slight change of total weight accompanies some chemical reactions. These experiments have been interpreted by some reviewers as throwing doubt upon the axiom of the conservation of matter. This axiom is not, however, incompatible with variation of total weight in chemical or even in physical changes. If it should be found, for example, that the weight of a given amount of lead and of a given amount of oxygen varied with physical and chemical conditions, a *standard state* of lead and a *standard state* of oxygen would have to be adopted in which state these substances would always have to be weighed, and the principle of the conservation of matter would have to be stated thus: Given so much lead and so much oxygen, measured by weighing under standard conditions, then, whatever changes these substances undergo, the amount of each is found to be unchanged if both are brought back to standard conditions and weighed.

Variation of weight with physical and chemical conditions would, no doubt, throw light upon the nature of gravitation, but if such a variation becomes established it will have but little disturbing influence upon the notion of the indestructibility of matter.

In the light of Professor Fessenden's electrical theory of gravitation, it would seem that the change of state most likely to produce a change of weight would be the dissolving of an electrolytic salt in water. For, assuming electrolytic dissociation to be a separating of positively and negatively charged atoms or *ions*, the region throughout which the electric force of the atom is exerted would be greatly extended by the dissociation.

THE ELECTRO-MAGNETIC THEORY OF RADIATION.

Professor M. Planck, of Berlin, published some months ago a derivation of the formula connecting energy and wave-length in the spectrum of a black body at a given temperature, the derivation being based upon the notion of an electrical resonator enclosed in a space surrounded by perfectly reflecting walls. It is remarkable that this formula should agree with the formula of Stefan obtained by thermodynamical considerations. In the *Verhandlungen d. Deutschen Phys. Gesellschaft*, for December 1900, Professor Planck has given an outline of some work, soon to be published in full, in which he applies the method of probabilities to the determination of the partition of energy among a vast number of electrical resonators enclosed within a reflecting boundary. A consequence of the theory developed by Professor Planck, which gives some check upon its legitimacy, is a formula which permits the calculation of the number of actual molecules of any salt in a gram-molecule (the number of atoms in a gram of hydrogen), the basis of the calculation being the energy curve of the spec-

trum of a black body as determined by Lummer and Pringsheim and by Kurlbaum. It is thus found that an atom of hydrogen weighs 1.64×10^{-24} grams. Professor Planck compares this result, together with other results depending upon it, with previous approximate determinations of this quantity, and he remarks that the values determined by his formula are *not approximations*, but that the calculations are absolutely valid, provided that his theory is true.

W. S. F.

NOTES ON INORGANIC CHEMISTRY.

IN an article by Berthelot in the *Annales de Chimie et de Physique* on Egyptian gold, it appears that in the earliest epochs, argentiferous alluvial gold was used for coins and other articles. Only later, from the time of Croesus down, was the gold refined. The period of manufacture can be approximately told by analysis, owing to the rarity of minerals which yield gold free from silver. Specimens of gold from the fifth and twelfth dynasties show about four per cent. of silver, but those from the Persian epoch consist of almost pure gold.

IN a recent number of the *Chemical News*, Dr. J. H. Gladstone gives an account of analyses made of specimens of gold leaf from Egyptian mummies, supplementing the work of Berthelot spoken of above. Down to the time of the eighteenth dynasty the foil is evidently made from the native alloy, containing from four to eighteen per cent. of silver, the latter alloy closely approaching electrum. The specimens from the first dynasty show a similarity of composition, coming from a single source, but those from the later dynasties differ among themselves, and evidently had different origins. Little copper is found in any of the foils. A very thin superficial crust of chlorid of silver is found in some of the foil, indicating a slow diffusion of one part of the alloy—the silver—till it reaches the outside surface, where it meets with the chloride that exists in the sands of the desert. That the Egyptians were acquainted with different qualities of gold is evidenced by the Harris papyrus, containing the annals of Rameses III., about B. C. 1200, where mention is made of gold, pure gold, good gold, white gold, best gold, gold of the second quality, fine gold of the land, gold of the land of Koebti, and of Kush.

THE recent cases of poisoning in England from arsenic contained in beer, and the differing results obtained by the chemists who have analyzed the beer in question, have given rise to an extended discussion in the *Chemical News* and elsewhere, as to the value of the tests for arsenic which are commonly relied upon to detect and estimate the amount of arsenic in suspected substances. This discussion is well timed, for, in the whole field of toxicology, no substance is more frequently to be tested for than arsenic. The test most generally depended on is Marsh's, and this is taught in almost every laboratory, of college and medical school. As a matter of fact, while this test is thoroughly reliable in the hands of a skilled analyst, it is beset with so many difficulties, which interfere with its accuracy, that it is of little value except when carried out by a chemist who has had long experience with it; indeed in the hands of a neophyte it is often wholly misleading. This is well shown in the recent cases, where the results obtained by the different analysts were very conflicting. On the other hand, even with unskilled chemists, Reinsch's test, when properly carried out, is thoroughly to be depended on, and is under ordinary circumstances more delicate than that of Marsh. Not the least of its advantages is the fact that it requires but a short time and the simplest apparatus only. Its value is well brought out by no less an authority than A. H. Allen, writing in the *Chemical News*. It is greatly to be hoped that the present agitation will result in placing the tests for arsenic on their proper relative basis.

SOMETIME since attention was called in this column to the fact that in the examination of quite a number of canned goods, tin was found present in every instance. A paper on the same subject by F. Wirthle has appeared in the *Chemiker Zeitung*, dealing with canned meat, mostly beef. The goods were from one to five years old, and in each case tin was found, and, as was also true of the experiments above referred to by Cowan and the writer, only the

slightest trace of lead. The quantity of tin found increased from year to year, as would have been inferred from the greater corrosion in the interior of the can in the older specimens. Wirthle concludes that the tin was in the form of the basic chlorid, and due to the action of the common salt in the meat, though in one instance the sulfid of tin was found. On the other hand tin was found by Cowan in canned fruits and tomatoes, and by Weber in canned pumpkins. It is greatly to be wished that a series of experiments should be carried out with a view of determining the effect of tin in small quantities upon the human organism, for little is known of its physiological action. From the amounts which are constantly ingested with canned goods, and seemingly without injury, it is to be inferred that it has little if any deleterious action, but it would be well were this established.

IN this connection, Roman and Delluc call attention in the *Journal de Pharmacie et de Chimie* to the presence of zinc in some samples of 95 per cent. alcohol examined by them. Since similar alcohol showed a reaction for zinc after being kept in contact with galvanized iron scrap for two days, the presence of the zinc in alcohol was accounted for by its having been kept, as is often the custom, in a galvanized iron vessel.

J. L. H.

THE U. S. NAVAL OBSERVATORY.

THE Naval Appropriation Bill, as passed by the Senate, contains the following provisions, authorizing the appointment of a board of visitors to the Naval Observatory and incidentally requiring the superintendent to be a line officer of the Navy:

For the expenses of the board of visitors to the Naval Observatory, two thousand dollars. There shall be appointed by the President from persons not officers of the United States a board of six visitors to the Naval Observatory, four to be astronomers of high professional standing and two to be eminent citizens of the United States. Appointments to this board shall be made for periods of three years, but provision shall be made by initial appointments for shorter terms so that two members shall retire in each year. Members of this board shall serve without compensation, but the Secretary of the Navy shall pay the actual expenses necessarily incurred by members of the board in the discharge of such duties as are assigned to them by the Secretary of the Navy or are otherwise imposed upon them. The board of visitors shall make an annual visitation to the Observatory at a date to be determined by the Secretary of the Navy, and may make such other visitations not exceeding two in number annually by the full board or by a duly appointed committee as may be deemed needful or expedient by a majority of the board. The board of visitors shall report to the Secretary of the Navy at least once in each year the result of its examinations of the Naval Observatory as respects the condition of buildings, instruments, and apparatus, and the efficiency with which its scientific work is prosecuted. The board of visitors shall prepare and submit to the Secretary of the Navy regulations prescribing the scope of the astronomical and other researches of the Observatory and the duties of its staff with reference thereto. When an appointment or detail is to be made to the office of astronomical director, director of the Nautical Almanac, astronomer, or assistant astronomer, the board of visitors may recommend to the Secretary of the Navy a suitable person to fill such office, but such recommendation shall be determined only by a majority vote of the members present at a regularly called meeting of the board held in the city of Washington. The Superintendent of the Naval Observatory shall be a line officer of the Navy of a rank not below that of captain.

This is what Senator Chandler promised as legislation to improve the management of the Observatory, but it is not likely to meet with the approval of those interested in the efficiency of the institution. A board of visitors of this character has but little real power, whereas it would serve as an excuse for any shortcomings there may be in the work of the Observatory. The board may recommend persons to fill vacancies in the staff, but it is not clear that the Secretary of the Navy is under any obligations to follow its recommendations. The astronomers apparently remain naval officers and the superintendent must be a line officer. These provisions make it still more desirable to urge the passage of Senator Morgan's bill, presented in the last issue of this JOURNAL.

THE DEPARTMENT OF AGRICULTURE.

THE provisions reorganizing certain divisions of the Department of Agriculture which, as we noted last week, were omitted from the appropriation bill as it passed the House have been reinserted by the Senate. The four bureaus provided and the staffs, as the bill now stands, are as follows:

Bureau of Plant Industry.—One plant physiologist and pathologist, who shall be chief of bureau, $3,000; 1 plant pathologist, $2,500; 1 botanist, $2,500; 1 pomologist, $2,500; 1 agrostologist, $2,500; 1 assistant pathologist, $1,800; 1 assistant botanist, $1,800; 1 assistant pomologist, $1,800; 1 assistant agrostologist, $1,800; 2 clerks, class 3, $3,200; 3 clerks, class 2, $4,200; 3 clerks, class 1, $3,600; 5 clerks at $1,000 each; $5,000; 2 clerks at $900 each, $1,800; 2 clerks at $840 each, $1,680 in all, $39,680.

Bureau of Forestry.—One forester who shall be chief of bureau, $3,000; 1 assistant forester, $2,500; 1 assistant forester, $1,800; 1 assistant forester, $2,000; 1 chief clerk, $1,800; 1 stenographer, $1,200; 1 field assistant, $1,500; 1 field assistant, $1,400; 1 field assistant, $1,200; 1 field assistant, $1,000; 1 field assistant, $720; 10 collaborators at $300 each, $3,000; 1 clerk class 3, $1,600; 1 photographer, $1,200; 1 computer, $1,000; 3 clerks, class 1, $3,600; 2 clerks at $1,000 each, $2,000; 4 clerks at $900 each, $3,600; 7 clerks at $720 each, $5,040; in all, $39,160.

Bureau of Chemistry.—One chemist, who shall be chief of bureau, $3,000; 1 assistant chemist, $2,500; 1 assistant chemist, $1,800; 1 assistant chemist, $1,600; 2 clerks, class 1, $2,400; in all, $11,300.

Bureau of Soils.—One soil physicist who shall be chief of bureau, $3,000; 1 scientist, $2,500; 1 scientist, 1,800; 1 scientist, $1,000; 1 chief clerk, $2,000; 1 stenographer, $1,200; 3 clerks, class 1, $3,600; 1 clerk, $1,000; 1 clerk, $840, 1 watchman, $720; 1 charwoman, $480; in all, $18,140.

SCIENTIFIC NOTES AND NEWS.

THE gold medal of the Royal Astronomical Society has been awarded to Professor E. C. Pickering, director of the Harvard College Observatory.

THE Amsterdam Society for the Advancement of Natural Science and Medicine has awarded its gold Swammerdam medal for 1900 to Professor Gegenbaur, of Heidelberg. The medal was established in 1880, and is awarded once in ten years for researches in the biological sciences, having hitherto been conferred on Professor C. Th. von Siebold and Professor Ernst Haeckel.

PROFESSOR E. A. SCHÄFER, of the University of Edinburgh, was presented, on January 30th, with a testimonial by his former pupils at University College, London. The presentation took the form of silver plate and a sum of money to be used for the foundation of a Schäfer physiological research medal.

PROFESSOR MATHIAS DUVAL, of the École de Médicine at Paris, who has been obliged by the condition of his eyes to forego work for two years, has undergone a successful operation. We understand that he will now be able to resume his important embryological researches, which have already given him a foremost place among the embryologists of the world.

AT a meeting of the trustees of the American Museum of Natural History, held on February 11th, the formal announcement was made of the gift to the Museum by Mr. J. Pierpont Morgan of the Tiffany collection of gems and of the famous Bement collection of minerals. Another very important gift is the ethnological collection brought together for the past twenty-five years by Andrew Ellicott Douglas. Mr. William E. Dodge was elected first vice-president of the Museum. Professor Henry F. Osborn was elected a trustee and second vice-president.

PROFESSOR J. PLAYFAIR MCMURRICH, of the Medical Department of the University of Michigan, has been asked by the Government of the Netherlands to take charge of, and make a report on, a collection of actinians secured from the neighborhood of the Malay Archipelago. The collection includes specimens from along the shore and from the deep sea.

PROFESSOR WILLIAM DEWITT ALEXANDER, head of the survey department of Hawaii, has resigned to accept a position on the United States Coast and Geodetic Survey. He will have charge of that branch of the department which has to deal with Hawaii and Samoa.

DR. JOHN S. BILLINGS, JR., has resigned his position of instructor in clinical microscopy in the University and Bellevue Hospital Medical College, New York, and has become assistant

director of the Bacteriological Laboratory of the Department of Health.

Colonel Peter Smith Michie, professor of natural and experimental philosophy at the West Point Military Academy, died on February 16th, of pneumonia. He was born in Scotland in 1839, graduated from West Point in 1863, and has been professor there since 1871. He was the author of a number of scientific and other works, including 'Elements of Wave Motion relating to Sound and Light,' 'Elements of Analytical Mechanics,' 'Elements of Hydro-Mechanics' and 'Practical Astronomy.'

Dr. J. H. Linsley, director of the Vermont Laboratory of Hygiene, died on February 17th at the age of forty-one years.

The expedition sent by the U. S. Naval Observatory to observe the eclipse of May 17th was expected to leave San Francisco for Manila on February 16th. From Manila it will be transported to Sumatra by a U. S. warship, and headquarters will be established at Padang about a month before the occurrence of the eclipse. The party includes Professor Skinner, of the U. S. Naval Observatory; Professor Barnard, of the Yerkes Observatory; Dr. Mitchell, of Columbia University; Dr. Humphreys, of the University of Virginia, and Mr. Jewell, of the Johns Hopkins University.

It is reported in the *N. Y. Evening Post* that Mr. Marshall A. Saville, of the American Museum of Natural History, has made important discoveries in the ruins of the Palace of Mitla, in the state of Oaxaca, Mexico, his excavations having disclosed a number of chambers under the palace.

Through the efforts of Mrs. William Bouton, the St. Louis Academy of Science has secured a fine collection of native and foreign butterflies.

Mr. J. Stanley-Gardiner, M.A., fellow of Gonville and Caius College, Cambridge, has presented the university with a collection of ethnological objects from the Maldive Islands and Minikoi Island.

The Medical Department of the University of Buffalo is in receipt of a gift of $50,000 for the purpose of erecting a laboratory to be devoted to research work and to be known as the Gratwick Research Laboratory.

We learn from foreign exchanges that at a recent conference of German biologists, held at Berlin, a resolution was passed calling the attention of the Imperial Government to the importance of establishing five floating stations on the Rhine for the purpose of biological investigation. Great stress was laid on the practical advantages which pisciculture would derive from these establishments, and it was resolved that if the Government failed to provide the necessary funds, an appeal should be made to the States of Baden, Bavaria, Alsace-Lorraine, Hesse and Prussia.

Professor J. A. Fleming reports that Mr. Marconi has succeeded in sending wireless messages between St. Catharine's, Isle of Wight, and the Lizard, a distance of two hundred miles.

The Portuguese Government is sending a commission to the Portuguese possessions in West Africa to study the sleeping sickness which occurs there.

It appears that the plague is increasing in Bombay, about 1,000 deaths having occurred during the last week of which reports are at hand.

It is proposed to hold an Industrial and Polytechnic Exhibition in Birmingham during the coming summer, with the object of raising funds to endow scholarships at the University for the benefit of the children of the working classes.

The inauguration of the work of the British National Physical Laboratory has been delayed by the opposition to the site at Richmond first proposed and by the alterations required in Bushy House, the building finally granted for the laboratory. The report of the executive committee for 1900, of which an abstract is given in *Nature*, describes the building and the alterations that are in progress. Bushy House itself will be used for the more delicate physical measurements; for the engineering work a new building, 80 by 50 feet in area, will be constructed. The work in prospect for the laboratory includes the connection between a magnetic quality and the physical, chemical and electrical

properties of iron and its alloys, with a view specially to the determination of the conditions for low hysteresis and non-agency; the testing of steam gauges, indicator springs and the like, for which a mercury pressure gauge will be provided; standard screw-gauges; electrical standards, and optical, thermometric and photographic tests.

WE learn from the London *Times* that, by his will, Mr. Philip Crowley, F.L.S., F.Z.S., of Croydon, who died on December 20th last, and whose collections of birds' eggs and of exotic butterflies are among the largest known to exist, bequeathed to the Trustees of the British Museum, from his natural history collections, whether of eggs or insects or other objects, all up to four species, and of eggs, if in clutches, four clutches, and if there should be more than four specimens in his collection to allow them to take half the extra, and should any species be useful or interesting by reason of variety or locality to allow them to take the whole series if they should think fit so to do—his idea being that what was really useful and wanted they might have, but that they should not take simple duplicates.

PENNSYLVANIA is a good second to New York in the forestry movement. Already it has secured 150,000 acres for its State forestry reservations. It will probably have 500,000 acres before the year ends, and looks forward to the acquisition of 1,500,000 or 2,000,000 acres. Its State College is now preparing to begin teaching practical forestry, and a bill has just passed the second reading in the House of Representatives which provides for the creation of a State Department of Forestry which shall be of equal importance with any other department of the Government. For years a campaign of education has been conducted in that State on very liberal lines, and it is largely to this that the popularity of forestry in Pennsylvania is due.

SANITARY science has scored two points of advantage during the month of January in two decisions of the New York Supreme Court, which make the pollution of streams by municipal corporations and private concerns actionable. Judge Houghton in General Term has granted an injunction against the city of Gloversvill for discharging its sewage into th Cayadutta creek, a tributary of Mohawk river. The Appellate Division has also affirmed the decision of Judge Stover in General Term, granting an indemnity against the Geo. West Paper Co., of Ballston, N. Y., for the pollution of the Kayaderosseras creek, a tributary of the Hudson river. Both suits were brought by private riparian owners, the former in spite of a bill passed by the New York Legislature of 1900, giving the city of Gloversvill the right of disposal now denied it by the Court.

A LAW has recently been passed which permits the French Government to forbid the manufacture and sale of absinthe and certain other fabricated articles of drink, recognized and declared to be dangerous by the Academy of Medicine. The Chamber has now voted to request the Academy to indicate those drinks which contain substances dangerous to the public health, so that their manufacture and sale may be prohibited.

THE Right Honorable R. W. Hanbury M.P., President of the Board of Agriculture, has appointed a committee for the purpose of conducting experimental investigations with regard to the communicability of glanders under certain conditions, and as to the arresting and curative powers, if any, of mallein when repeatedly administered. The committee will consist of Mr. A. C. Cope, chief veterinary officer of the Board of Agriculture (chairman); Professor J. McFadyean, principal of the Royal Veterinary College; Mr. William Hunting, one of the veterinary inspectors of the London County Council; Mr. J. McIntosh McCall, assistant veterinary officer of the Board of Agriculture; Mr. H. A. Berry, of the Board of Agriculture, will act as the secretary to the committee.

BEFORE the Pan-American Medical Congress, which met recently at Havana, the board which has been engaged in the investigation of yellow fever, consisting of Drs. Reed, Carroll and Agràmonte, made a report. According to despatches to the daily papers, it was stated that two of the main conclusions were that the specific cause of the disease is unknown, and that it can be carried only by mosquitoes. Conse

quently the disinfection of clothing and houses is useless. The fever can be produced by a subcutaneous injection of blood from a patient who must have had the disease for not more than two days. Mosquitoes must also bite the patient during the first two days of his illness or they cannot transmit the disease. The board kept an infected mosquito for fifty-one days, when it was allowed to bite a person who contracted the disease. The board differs from Dr. Finlay in that the latter holds that more than one kind of mosquito can convey yellow fever. The board says there is only one kind that can do so. Dr. Finlay also says that a mosquito can transmit the disease the fourth or fifth day after biting a patient, while the board says that twelve days must intervene. The board reported that non-immunes were allowed to sleep in infected clothing and bedding, but none contracted the disease. A member of the Congress objected that these so-called non-immunes might really have been immunes. The board replied that two of these were subsequently subjected to the bites of infected mosquitoes and contracted the disease. The moral aspect of the experiments was touched upon. It was pointed out that members of the board were themselves bitten and one of them died. Yellow fever is not due to dirt. It may occur in the cleanest localities. Dr. Wilde of the Argentine Republic proposed the creation of an international yellow fever board to study means of exterminating the disease.

THE Illinois Society of Engineers and Surveyors held its sixteenth annual meeting at Bloomington on January 23d–25th.

AT a meeting in San Francisco a committee of fifteen was authorized for the preparation of plans for a Pacific Coast Medical Association.

A CONFERENCE of science masters in public schools was held recently in the rooms of the University of London, at South Kensington, with Sir Henry Roscoe in the chair and about fifty members in attendance. The subjects discussed included the order of science teaching, the coordination of the teaching of science and mathematics, natural history societies, and science and examinations.

The Council of the St. Louis Academy of Science announces that it has arranged for a series of addresses on the progress made in the several departments of pure and applied science during the nineteenth century. These addresses, to which the public is welcome, are given at the Academy Rooms, 1600 Locust street, at the second stated meeting of each month, at 8 P. M. Subject to revision due to unforeseen causes, the following program is announced for these meetings:

January 21st, Rev. M. S. Brennan, 'Astronony.'

February 18th, Professor J. L. Van Ornum, 'Engineering.'

March 18th, Dr. E. H. Keiser, 'Chemistry.'

April 15th, Mr. C. F. Marbut, 'Geology.'

May 20th, Professor George Lefevre, 'Zoology.'

October 21st, Professor F. E. Nipher, 'Physics.'

November 18th, Mr. Herbert F. Roberts, 'Botany.'

December 16th, Mr. F. Louis Soldan, 'Education.'

THE public lectures under the auspices of the department of zoology of Columbia University are being given this year by Dr. Gary N. Calkins, the dates and titles being:

February 15—'The Simplest of Living Animals. General Sketch.'

February 19—'The Sarcode Animals; Naked bits of Protoplasm.'

February 26—'The Flagellated Organisms, the Most Important Group, theoretically, of the Protozoa.'

March 1—'The Malarial Germ and other Sporozoa.'

March 5—'Infusoria, the Highest Type of Protozoa.'

March 8—'The Loss of Vitality in Protozoa and its Renewal through Conjugation.'

March 12—'The Protozoon, a Physiological Machine.'

PROFESSOR NIPHER, of Washington University, is still making progress in his photographic work. If his pictures are unsatisfactory on first development, he destroys the picture chemically and starts again with a clean film. If the picture is started as a negative in the dark room and is unsatisfactory, he first dissolves the picture with the fog on the plate, then a fresh picture is developed on the same film. This picture may be a negative in the dark room, or it may be a positive, if the development takes place in the light. In a similar way, if the first picture is a positive, the second picture may be either a positive or a negative, according as the second development is in the light or in the dark room. There is a great advantage in start-

ing the secondary treatment with a clear film. A picture started as a negative may be reversed by turning on the light, but the high lights are already dark and the shadows must then become dark in contrast with them. The whole picture will then be very dark. By this new process the second picture may be as perfect as if the original treatment had been properly started.

THE directory of the Washington Academy of Sciences and affiliated societies for 1901, compiled by Dr. Marcus Baker, and corrected to about January 10th, has been distributed to members. The membership of the societies, excluding corresponding members in some cases, is 2,557 and the number of persons 2,013. The membership is distributed among the different societies as follows:

Academy of Sciences	291
Anthropological Society	125
Biological Society	171
Chemical Society.	121
Entomological Society	52
National Geographic Society	1059
Geological Society	147
Columbia Historical Society	180
Medical Society	309
Philosophical Society	102

THE American Metrological Society has issued a circular, primarily for distribution among members of Congress, entitled 'A Few Reasons Why the Metric System of Weights and Measures should be Adopted in the United States.' It presents very clearly the great advantages of the metric system and should be widely circulated. Copies can probably be obtained from the president of the Society, President T. C. Mendenhall, Worcester, Mass., or the secretary, Professor J. H. Gore, Columbian University, Washington, D. C.

IT is proposed in Dundee to erect a granite monument over the grave of James Bowman Lindsay, in the Western Cemetery of the city. *Nature* calls attention to the fact that Lindsay was a remarkable man, whose memory should not be permitted to fade. He was born in 1799, and taught electricity, magnetism and other subjects in Dundee for many years, dying there about forty years ago. In 1834 he foresaw that 'houses and towns will in a short time be lighted by electricity instead of gas, and machinery will be worked by it instead of steam.' This prediction was the result of his own observations of effects produced by the electric current, and not merely imaginative suggestions. In 1854 Lindsay transmitted telegraphic signals through water electrically; and when the British Association visited Aberdeen in 1859, he demonstrated the success of his method by transmitting signals across the harbor. He also read a paper upon it, entitled, 'Telegraphing without wires.'

IT is stated in the *Lancet* that, in consequence of a movement which was started two years ago, a salmon hatchery for the river Tweed has just been erected. The hatchery, which is fitted with all the modern improvements, is situated at East Learmouth, about a mile from Cornhill-on-Tweed, on an excellent site which has been granted by Earl Grey. The management of the hatchery is under the supervision of Mr. F. J. Douglas, Springwood Park, Kelso, and Mr. George Grey of Millfield. The hatchery is a private undertaking with which the River Tweed Commissioners have no official connection, and the cost of which has been subscribed to by every river proprietor from Torwoodlee to Tillmouth. The building is 48 feet long by 20 feet wide and seven feet high inside. It is fitted with 12 boxes capable of holding in all 18 grilles, so that the 12 boxes combined have a capacity for about 300,000 salmon ova. If the fry were hatched three times in a season the output would not fall far short of 1,000,000 salmon fry. The water supply is carefully filtered before passing into the boxes. There is in the hatchery an impounding tank of 1,100 gallons capacity for keeping the salmon in after capture until they are ready for spawning. The young fry will be kept until they are six months old. For this purpose six ponds are to be constructed 40 feet long by eight feet wide by four feet deep. There are those who think that fish-culture may play an important part from a medical point of view in the future.

THE Prussian Minister of Public Instruction has issued an order regulating experiments in hospitals which is quoted by the London *Times* as follows: "I hereby call the attention of those who have the management of clinical and

polyclinical hospitals and similar institutions to the fact that medical operations for any purposes save those of the diagnosis, cure, and prevention of disease are forbidden, even when otherwise permissible from the legal and moral point of view—(1) in the case of a person who is a minor or for other reasons is not entirely responsible; (2) in cases where the person in question has not explicitly given permission for the operation; (3) in cases where this permission has not been preceded by a proper statement of the injurious consequences which might possibly result from the operation. I likewise order that operations of this nature shall be undertaken only by the director of the institution himself or by his special authorization. Whenever such an operation is performed the register of the case must contain a statement that the above conditions have been fulfilled, and must also give a detailed account of the circumstances. The existing regulations affecting medical operations for the purposes of the diagnosis, cure, or prevention of disease are not affected by these instructions."

UNIVERSITY AND EDUCATIONAL NEWS.

BY the will of the late Professor Edward Edridge Salisbury, Yale University will receive on the death of Mrs. Salisbury a certain part of the residue of the estate, the amount being estimated at $150,000. One-half of the sum is to provide an additional income for the Salisbury professorship of Sanskrit and comparative philology, and the other half is to accumulate until it reaches $100,000, when the income is to be used for such purpose as the trustees may determine.

BY the will of the late J. A. Vanderpoel, Rutgers College will receive $25,000 on the death of Mrs. Vanderpoel, the money to be used for scholarships in chemistry.

A BILL has been introduced at Albany providing for the establishment of a State electrical school at Schenectady, which would be a part of Union College. The bill appropriates $150,000 for the establishment of the school and $25,000 for maintenance. Union College is to offer 100 scholarships and the General Electrical Company is to give the use of its shops for observation and instruction.

A BILL has also been introduced at Albany appropriating $100,000 for the establishment of a State Veterinary College for the eastern part of the State to be consolidated with the College of New York University.

THE Paris faculty of medicine has established a school for the study of tropical diseases, with special chairs of bacteriology and parasitology.

A MEMORIAL to the Secretary of State for India, begging for an inquiry into the recent dismissal of seven of the staff of Coopers Hill College, has been signed by Lord Kelvin, Lord Lister, Lord Rayleigh, Sir Frederick Abel, Sir Frederick Bramwell, Sir William Huggins, Sir Norman Lockyer, Sir Andrew Noble, Sir William Crookes, Sir Archibald Geikie, Sir Henry Roscoe, Professor Dewar, Professor J. J. Thomson, Professor Armstrong, Professor Marshall Ward, Professor Ewing, Mr. W. H. M. Christie, Mr. R. T. Glazebrook, Mr. W. N. Shaw, and by some seventy other Fellows of the Royal Society.

AT the Rush Medical College, University of Chicago, Dr. G. S. Lingle has been appointed professor of experimental physiology, and Dr. W. D. Zoethout laboratory professor of neurology.

IT is reported that Professor Frank Thilly, of the University of Missouri, has been offered the chair of ethics at Leland Stanford Junior University.

AT the Massachusetts Institute of Technology the following promotions have been made: Dr. Henry Fay, assistant professor of analytical chemistry and metallography; Dr. James F. Norris, assistant professor of organic chemistry; Dr. F. H. Thorp, assistant professor of industrial chemistry, and Dr. W. R. Whitney, assistant professor of theoretical chemistry and proximate analysis. In the department of physics, Messrs. L. Derr, C. L. Norton and Dr. G. V. Wendell have been promoted to assistant professorships.

DR. F. SCHENCK, of Würzburg, is to succeed Kossel as professor of physiology at Marburg.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, MARCH 1, 1901.

THE AMERICAN SOCIETY OF BACTERIOLOGISTS.

THE American Society of Bacteriologists held its second annual meeting at Baltimore, at the end of December under the presidency of Professor Wm. T. Sedgwick, whose address has already been published in SCIENCE. The following papers were presented :

Distribution of Bacillus ærogenes capsulatus : W. H. WELCH.

Dr. William H. Welch presented the results of investigations of Mr. L. K. Hirshberg in the Pathological Laboratory of the Johns Hopkins University. There can be no question but that the bacillus discovered by Welch in 1891 and fully described by Welch and Nuttall in the following year is identical with Fraenkel's *B. phlegmones emphysematosæ*, with Veillon and Zuber's *B. perfringens*, and with Schattenfroh and Grassberger's *Granulobacillus saccharobutyricus immobiles liquefaciens* described in 1900. It is possible that Klein had in his cultures *B. ærogenes capsulatus*, but his description of his *B. enteritidis sporogenes* can not be reconciled with the properties of the former bacillus, especially his statements as to motility and peptonization of milk. It has already been demonstrated by Welch, by Howard, and by Hitschmann and Lindenthal that *B. ærogenes capsulatus* is a widely distributed organism, its natural habitats being especially the intestinal canals of man, animals

and the soil. Mr. Hirshberg has, during the past summer, made a systematic study of the distribution of this bacillus in various situations. Various methods were employed for its isolation, one of the most useful being the inoculation into the circulation of rabbits, which were then killed according to the procedure described by Welch and Nuttall. In each instance the bacillus, if found, was isolated in pure culture, and identified by its characteristic properties. *B. ærogenes capsulatus* was found by Mr. Hirshberg regularly in the feces of man (being isolated from all parts of the intestinal canal), of swine, of dogs and of cats, and was found with varying frequency, as a rule, in 50 to 80 per cent. of the animals examined, in the feces of rabbits, guinea-pigs, mice, rats, chickens, pigeons and cows. It was likewise obtained from the excrement of flies hovering around the bodies of infected animals or human cadavers. It was isolated constantly from garden earth, rarely from street dust. It was detected four times out of eighteen examinations of dust swept from the floors of hospital wards, the dispensary or the laboratory. Once it was obtained in scrapings from the human skin. It was isolated twice from cesspools. The results of Schattenfroh and Grassberger concerning the presence of this bacillus in market milk were confirmed. In the light of these and previous investigations *B. ærogenes capsulatus* must be regarded as the most widely distributed of bacteria.

The Bacterial Condition of City Milk and the Need of Health Authorities to prevent the Sale of Milk containing Excessive Numbers of Bacteria: H. W. Park, New York.

The author raised the question whether it is possible for health boards to set a limit to the number of bacteria which milk may contain, and above which its sale could be prohibited. During the coldest weather the milk in New York City averages about 250,000 bacteria per cc., during cool weather about 2,000,000 and during hot weather about 5,000,000. The milk in other large cities is, from all accounts, in about the same condition. The above statement does not apply to the special milks which contain only from 5,000 to 20,000 bacteria at the different seasons of the year. In answer to the question whether these enormous numbers of bacteria found in milk during the hot weather are harmful, reference need only to be made to the universal clinical experience that a great number of children in cities sicken on the milk supplied in summer; that those who are put on milk that is sterile, or contains few bacteria, as a rule, mend rapidly, while those kept on the impure milk continue ill, or die. We probably have, as yet, insufficient knowledge to state just how many bacteria must accumulate to make them noticeably dangerous in milk, but it is a safe conclusion that no more bacteria should be allowed than it is practicable to avoid. Any intelligent farmer can use sufficient cleanliness and supply sufficient cold, with almost no increase in expense, to supply milk 24 to 36 hours old which will not contain in each cc. over 100,000 bacteria, and no milk poorer than this should be sold. The most deleterious changes which occur in milk during its transportation are now known to be due to the changes produced by bacterial growth and activity. These add to the milk acids and distinctly poisonous bacterial toxins to such an extent that much of the milk, by the time it is used in summer, has become decidedly injurious to invalids and infants. While it is the universal custom of the health authorities to guard their milk in many ways, they nevertheless entirely fail to prevent the sale of milk rendered unfit for use through excessive numbers of bacteria and their products. This seems all the more remarkable when we consider how comparatively easy the

test, and how rapidly the farmer and middle-man could greatly improve the bacterial purity of their milk if only their dense ignorance and lack of desire to improve could be removed.

Duration of Life of Typhoid Bacilli, derived from Twenty Different Sources, in Ice; Effect of Intense Cold on Bacteria: W. H. PARK, New York.

Cultures derived from twenty different cases of typhoid fever were grown 28 hours in nutrient agar. From each one a loopful was inoculated into 300 cc. of sterile distilled water and this was poured into thirty glass tubes. These were kept in a room averaging 23° F. (−5° C.). From time to time a tube was removed and the number of bacilli which should develop in nutrient agar tested. The following table gives the results:

Number of weeks frozen.	Per cent. of bacilli living.	Per cent. of cultures living.
0 (Original)	100	20
½ week	42	20
1 week	14	20
2 weeks	7.50	20
3 "	.4	20
5 "	.11	18
7 "	.09	18
9 "	.05	17
12 "	.005	11
15 "	.002	8
18 "	.0001	3
22 "	none	0

Watery suspensions of typhoid, colon diphtheria and hay bacilli and of the *Staphylococcus pyogenes aureus* were placed in small tubes and dropped into liquid air. From time to time the tubes were removed and the contents plated in nutrient agar. The percentage living was as follows:

Per cent. living after exposure of	Typhoid.	Colon.	*Staph.*	*B. sublitis.*
3 min.	18	19		
20 "	10	11	85	80
60 "	7.5	8	51	67
130 "	3	5.5	27	55

The virulence of the organisms was only slightly diminished by this intense cold for two hours.

The Use of Paraffin to exclude Oxygen in growing Anaërobic Bacteria: W. H. PARK.

Nutrient glucose bouillon in tubes or flasks covered with a layer of paraffin, melting at 42° C., has proved very useful in the devolopment of tetanus cultures and toxins and of other anaërobic bacteria. With bacteria not possessing spores the medium is quickly cooled and inoculated and then covered by a layer of very hot sterile paraffin. The accumulation of gas forces the paraffin up in the tube or flask, but does not allow the entrance of oxygen. When absolute exclusion of oxygen is desired, the tubes with their layer of paraffin are sterilized in an autoclave which renders them free from oxygen. Spore-bearing bacteria are inoculated through the liquid paraffin before the bouillon is fully cooled. Bacteria without spores are inoculated by breaking through the paraffin film or by heating the paraffin in a gas flame. A pipette can then be carried through the hot paraffin into the cool liquid below. The paraffin layer has also been found useful in preserving media from drying or from changes due to the absorption of gases of the air.

Bacteria in the Ames Sewage Disposal Plant: L. H. PAMMEL, Ames, Iowa.

The author describes a sewage plant designed for the disposal of the sewage of about six hundred people. The plant is of the ordinary type, consisting of two beds, each covering about 0.2 of an acre. The filtration in the beds was at the rate of about 100 gallons a day, per acre. The whole plant was installed for about $3,000. The efficiency of the filter bed was shown by bacteriological analysis. The effluent of the filter bed for 1899 showed an average of 5,127 bacteria per cubic centimeter, and at no time did it rise over 11,075 per cc.

The number of bacteria in the water in the tank varied largely with the temperature, rising in September to 9,000,000, and falling in colder weather to a little over a hundred thousand in March. The filter bed was, therefore, extremely efficient in removing bacteria. In the study of the species of bacteria found in the effluent, some of the common sewage types were found. The author found, also, in this effluent, *Bacillus prodigiosus.* This was interesting inasmuch as it made its appearance in the sewage after it had been introduced into the laboratory in Ames. It was not believed, however, to be a native of the locality, but an introduced species.

Variations of Bacillus rosaceous metalloides (Dowdeswell): NELSON G. DAVIS, Lewisburg, Pa.

During the summer of 1896 a series of experiments was begun on the variations of *Bacillus rosaceous metalloides.* In making a pure culture of the organism, it was noticed that one colony was much paler in color than the others. No pigment appeared until the colony was some days old. Replating from this colony, all the daughter colonies were colorless until the fourth day, when a pale pink pigment appeared. After a time the characteristic metallic luster became visible. A continuation of the replating and selection of colonies was kept up for nine months. By that time cultures of the *Bacillus rosaceous* varying in color from colorless to a deep red, deeper than the original variety had been obtained. The darkest variety of all appeared as a 'sport'; so did also the first pale colony. The other variations appeared as gradual modifications. An attempt was made to produce a variety that would not liquefy in gelatin. This was unsuccessful, although in two instances the colonies were obtained, much slower than usual in their action. Similar selection experiments demonstrated great varieties in the size of the organism. After about two hundred replatings, there appeared in one of the gelatin plates a colony in which the length of the elements was the same as the breadth. In other words, it appeared to be a coccus $0.5\,\mu$ in diameter, and was so described by students. This variety was cultivated in various media, at various temperatures, in light and darkness. It remained constant in size.

Some Varieties of Bacillus pyocyaneous found in the Throat: F. P. GORHAM, Providence, R. I.

Bacillus pyocyaneous is a comparatively frequent form in the nose and throat. Two varieties can be distinguished, one producing both pyocyanin and a fluorescent pigment, the other producing only pyocyanin. These forms are often present in almost pure culture, and may persist in the same individual for several months. The cultures are virulent for guinea-pigs and rabbits.

Demonstration of Photogenic Bacteria: F. P. GORHAM.

Cultures of several varieties of phosphorescent bacteria were exhibited at the evening session. They were growing on fish, fish-agar and fish-bouillon. Some of the cultures were remarkably luminous.

Bacillus Lactis Viscosus, a Cause of Ropiness in Milk and Cream: ARCHIBALD R. WARD, Ithaca, N. Y.

The writer has closely observed the occurrence of the milk fault, known as 'ropy milk,' in the creameries of three different milk dealers in widely separated localities in New York State. *Bacillus lactis viscosus*—Adametz, has been found to be the cause of trouble in each outbreak. The identification of the organism found in the ropy milk was confirmed by Dr. Adametz, who studied a culture sent for identification, and pronounced it identical with the one first de-

scribed by himself. Attention is called to the fact that in several text-books there occurs an erroneous statement to the effect that the organism brings about the viscid condition in milk very slowly, and that it is, therefore, of no practical importance to dairymen. The statement is founded upon a misconstruction placed upon a sentence written by Dr. Adametz. The organism is found in water, and multiplies at a temperature as low as 8° C. These characteristics, together with the method of keeping the milk, account for the persistence with which ropy milk appears on a milk route when the creamery is once infected. In all the cases coming under my observation, the milk dealer has cooled the milk in long, open-topped cans standing in ice water. In each case the ice water was found to contain the organisms. These might readily be introduced into the milk by the spattering of water incident to the removal of cans, addition of ice, etc. That the ice water was the immediate cause of trouble was indicated by an experiment in which potassium bichromate was added to the ice water in the proportion of one part to one thousand parts of water. The trouble did not recur in those cans of milk which were placed in the water after the addition of the disinfectant. In this case scrupulous care was observed in sterilizing vessels which had been infected.

Concerning the Presence of Streptococci in the Healthy Udder of a Cow: R. C. REED and A. R. WARD.

At intervals between November, 1897, and July, 1900, the presence of streptococci in the freshly drawn milk of a cow in the Cornell University herd was noted. While some cases of mammitis, associated with streptococci, were known to have occurred in the herd during this period, yet we had no record that this cow ever suffered an attack. The fact that she led the herd in butter production during the period in which the streptococci were observed in the milk indicates that the cow was not suffering from a chronic form of the disease. This fact is significant in view of the serious effect of mammitis on the secretion of milk. The slaughter of the animal in the summer of 1900 afforded an opportunity to study the bacterial flora of the udder by means of cultures made directly from all parts of the gland. In addition to some organisms commonly found in the udder, streptococci appeared in all the thirty-six cultures. In conjunction with the streptococcus under consideration one culture from a sporadic case of mammitis and one from an epizootic of the same disease were studied. In their cultural, morphological and pathogenic properties the streptococcus from this healthy udder was indistinguishable from those isolated from the cases of mammitis. None were pathogenic to guinea-pigs or rabbits, but all three induced mammitis when injected into a healthy udder. While these observations are incomplete, they can not but suggest the idea that the streptococci associated with mammitis may, like the specific organisms of diphtheria and pneumonia in the healthy throat, be harbored in the healthy udder without producing disease.

Immunization of Animals to Rattlesnake Venom, and some studies of Antivenine: JOSEPH MCFARLAND, Philadelphia, Pa.

In order to determine whether the experimental immunity to serpents' venom, upon which Calmette has done such interesting work, applied equally well to venoms of the cobra and rattlesnake. The endeavor was made about two years ago to immunize several horses to the venoms of American rattlesnakes. The problems encountered were more difficult than those with which Calmette had to contend, because of the intense local irritative action

of the venom. Cobra venom possesses this local irritative property in very slight degree, and Calmetti found that when the cobra venom was heated to 70°C., for an hour, it was completely set aside. It was found, however, that when rattlesnake venom was heated sufficiently to annul its irritative qualities its toxic properties were almost destroyed. The horses at first received heated venom, but later were injected with solutions of the dried venom in its normally active state. The injections were given subcutaneously and were followed by enormous edemata, necroses and sloughs, so that after determining that no immunity to the local action developed, this method was abandoned and the intravenous used. The interior of the vessels showed no sign of injury, probably because the well-diluted venom at once met with greater dilution in the circulating blood. No local or other irritative disturbances followed the intravenous injection, but the nervous impression was profound; the horses often fell, and remained unconscious for some minutes after injection, and, to prevent injury to themselves, required to be suspended. Two of three horses died before antivenine developed from the damage to their tissues caused by the irritation of subcutaneous injections. The third horse lived for a long time and developed a very marked immunity associated with the appearance of antivenine in the blood. The death of the horse finally resulted from the unfortunate accidental entrance of some venom into the sheath of the jugular vein during one of the injections. Not being immuned to its irritant effects, the venom produced a local edema which killed the animal by suffocation. The antivenine produced by this horse was of such strength that 2 cubic centimeters of the serum protected a rabbit—an adult rabbit—against a fatal dose of either rattlesnake (0.002 gram) or cobra (0.001 gram) venom.

How can Bacteria be Satisfactorily Preserved for Museum Specimens? H. W. CONN, Middletown, Conn.

A method of preparing museum specimens was described. A 2-per-cent. agar culture medium is placed in large test tubes and tilted so as to make agar slants. The tubes are left undisturbed for from six to eight weeks, in order to allow the surplus moisture to evaporate. They are then inoculated in long streaks and immediately sealed with plaster of Paris and paraffin. The cultures grow for a few days, then cease growing, and remain unaltered indefinitely. No disinfectant is needed. The cultures remain alive for many months, and possibly for years. The method is satisfactory except for one fact—the atmosphere in the tube becomes filled with moisture and this condenses on the inside of the tube with changes of temperature. No method has yet succeeded in avoiding this condensation of water, which in most cases renders the tube cloudy, and injures its value as a display specimen.

The Effect of Salt Solution and other Fluids on Bacteria compared with Serum Reaction: ADOLPH GEHRMANN.

The author described, first, a series of experiments to determine the effect upon bacteria (typhoid and colon bacilli) of transferring them from one solution to another in which the percentage of salt is less. These experiments showed that, if the salt was not stronger than one per cent., the solution did not materially injure the bacteria, and did not produce the plasmolysis and plasmotypsis described by Fisher. Solutions of one per cent. have an inhibiting action and cause typhoid cultures to develop long chains and to lose their motility. A second series of experiments tested the effect of salt in the diluting fluids which were used in making the serum tests. Distilled water, normal salt

solution, and a bouillon culture fluid, made both with .5-per-cent. salt and without salt, were compared side by side, and were found to be fully equivalent. Blood diluted with any of the above readily produced the agglutination test, about the same time elapsing in all cases before the agglutination occurred. A further series of experiments tested the influence of the viscosity of fluids upon motile bacteria, as aiding in explaining agglutination. These experiments showed that the typhoid bacillus becomes readily agglutinated in fluids having considerable viscosity. For testing this phenomenon, gelatin and egg albumen were used both of which caused the bacilli to adhere in clumps, which, however, were dissipated if the solutions were diluted. While these observations were regarded as having significance in interpreting the serum test, the author was of the opinion that, when properly conducted, the agglutination obtained in the serum test can readily be distinguished from that which is the result of such physical conditions.

Growth of Bacteria in the Presence of Chloroform and Thymol: ERWIN F. SMITH, Washington, D. C.

As an illustration of the frequent dependence of bacteriologists and physiological chemists upon chloroform as an antiseptic, the speaker cited various passages from the recent valuable English work of Green on 'The Soluble Ferments and Fermentation.' In this book there are many statements and implications that animal and vegetable infusions can be preserved from bacteria growths during their examination by the addition of chloroform. Twelve micro-organisms are known which grow readily in test-tube cultures of milk, beef bouillon, etc., to which an equal volume of chloroform has been added. This probably by no means exhausts the list. Test-tube cultures of eight of these organisms growing readily in presence of chloroform were exhibited. Two organisms are also known which grow readily in beef bouillon to which thymol has been added. It would appear, therefore, that there is no general rule, but that each bacterial organism must be tested by itself as to the effect upon it of chloroform, thymol, etc. If chloroform is used to preserve fluids or macerations of animal and vegetable substances from the growth of micro-organisms, it would be well to seal the flasks and keep them constantly agitated. Moreover, if one would be certain of their continued sterility, the freedom from bacteria growth of the substances under examination must be determined from time to time by microscopic examination and by cultures made from the fluids or macerations, otherwise, especially where bacterial organisms are able to produce the same substances as those sought for in plant or animal tissue, *e. g.*, cytase, diastase, etc., there can be no certainty as to the exact origin of the substance in question.

Infection by means of Modeling Clay: M. O. LEIGHTON, Montclair, N. J.

The author's attention is drawn to the possibility of the distribution of infectious disease among school children by the common use of model-clay. In the ordinary schools such clay, after having been used by one student, is returned to the stock box and subsequently used again. Study of clay thus obtained from schools showed bacteria to be tolerably abundant in the clay. The species of bacteria identified were those which ordinarily occur in pus formations, thus showing that clay may be capable of distributing these organisms. An attempt to sterilize clay showed that the only efficient means of accomplishing this purpose is by the use of superheated steam under the pressure of 15–20 pounds for 45 minutes. Next, an attempt was made to

determine how long certain pathogenic bacteria could remain alive in the clay. Sterilized clay was inoculated under proper precautions, with the bacilli of typhoid, diphtheria and tuberculosis. The clay was then kept moist and warm, and studied periodically for the presence of these organisms. The results were, briefly, as follows: *B. Typhi abdominalis* grew vigorously after having been enclosed in the clay for 32 days. After that no colonies were found. *B. diphtheria* grew after having been enclosed in the clay for 18 days. *B. tuberculosis* was alive after 18 days. How much longer the latter two bacilli would remain alive in the clay the author did not determine. The experiments, however, sufficiently demonstrate that the indiscriminate use of modeling clay in the schools is unwise, and liable to distribute communicable diseases, if such are present among the pupils.

A Preliminary Report upon a Hitherto Undescribed Pathogenic Anaërobic Bacillus: Norman Harris, Baltimore, Md.

This organism was isolated, post-mortem, from one of several abscesses in the liver of a man who had entered the service of Professor Halsted in the Johns Hopkins Hospital of Baltimore. He complained of great pain in the hepatic region of the abdomen, accompanied by nausea, vomiting and jaundice. Blood examination showed a marked leucocytosis. Exploratory laparotomy was performed and the condition was found to be one of multiple abscess of the liver, and beyond radical treatment. The patient died the fourth day after operation. The autopsy disclosed the presence of numerous abscesses throughout the liver, as well as in the right lung and spleen. Petri dish cultures were made in plain and in hydrocele fluid agar and grown both aërobically and in an atmosphere of hydrogen for a period of seventy-two hours. All dishes showed no growth, except the undiluted hydrocele fluid culture which had been in the hydrogen atmosphere. This developed four colonies surrounded by a halo of growth, and these appeared to arise from small particles of liver detritus. Subcultures were successfully grown only when the media were made up with hydrocelic fluid or human blood, and when oxygen was excluded. Characteristics: the organism is a bacillus which in general is not minute, although its size varies somewhat on the various media. It may occur as cocci diplococci, very short rods, longer rods, filaments, or more rarely as chains of cocci or very short rods. Occasionally some rods are seen to have swollen ends, or may show distinct polar granules, or may be slightly curved. It is non-motile; it is decolorized by Gram's method of staining; it does not liquefy gelatin; it does not appear to have spores; its thermal death point is an exposure of ten minutes at 50° C. In all media it gives off a very strong fecal odor, and forms gas from the ordinary and sugar-free beef broth, when made up with either hydrocele fluid or blood. It likewise actively ferments glucose, forming CO_2, H, and H_2S, the gas igniting readily. Experimentally, lesions similar to those found in the human subject were produced in rabbits and guinea-pigs, and mice succumbed to subcutaneous inoculation with a local necrotic lesion only. The name proposed for the organism is *Bacillus mortiferus* or *Bacterium mortifer*. The organism differs essentially from any of anaërobic bacilli hitherto described.

Concerning the Theories of Silage Formation: H. L. Russell and S. M. Babcock, Madison, Wis.

The authors instituted along series of experiments to determine whether the changes that take place in the silo are due to micro-organisms, as has been believed, or to other

kind of action. Their conclusions are: (1) Silage can be made under conditions that exclude bacterial activity. (2) The initial heating of the silage is due, mainly, to the respiratory processes of the cut plant tissues. (3) The peculiar characteristic of good silage is due, not to bacteria, but to changes inaugurated under the more or less direct control of the activity of the protoplasm of the plant tissues. The acids of silage seem to be for the most part a product of the intra-molecular respiration, and in quantity are roughly proportional to the length of time that ensues before the cells stop respiring. This fact explains the reason that silage from immature corn has a higher acidity, and is more likely to undergo putrefactive changes due to bacteria growing in the succulent tissues than silage made from mature corn. (4) The aroma of good silage can be produced under conditions in which all vital processes are suspended. This seems to point strongly to the idea that enzymes are operative in the production of this aroma. It has previously been shown that such ferment bodies are liberated from dying vegetable cells and that they continue to act after the cells lose their vitality.

Demonstration of some New Laboratory Devices: F. P. GORMAN, Providence, R. I.

The following laboratory devices were demonstrated: (1) The application of the incandescent electric lamp to heating incubators, water and paraffin baths. (2) Culture tubes with etched surface for writing data. (3) Large slides for the examination of series of cultures. (4) Cotton 'silver' for plugging tubes, etc.

A Low Temperature Incubator: E. H. WILSON, Brooklyn, N. Y. (Read by title.)

Preservation of Sputum for Microscopic Examination; A New Fermentation Tube: A. ROBIN, Newark, Del.

The author has experimented with some of the active germicides with a view to preserving tuberculosis sputum. Carbolic acid, 5-per-cent. solution; trikresol, 2-per-cent.; formaldehyde, 5-per-cent., and hydrochloric acid, 10-per-cent., were added to sputum containing large numbers of tubercle bacilli. The coagulation resulting from the addition of carbolic acid or trikresol to sputum containing pus was largely overcome by vigorous shaking, the coagulation being thus finely broken up. The sputum was examined at the end of 24 to 48 hours. Weekly and then monthly examinations were made for a period of four months. Except when hydrochloric acid was used, the bacilli were found well preserved and, if anything, stained much more deeply. HCl, on the other hand, seemed to have either so disorganized the bacilli or so changed their staining properties that they could not be

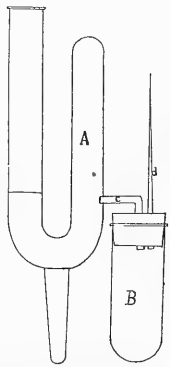

FIG. 1. A New Fermentation Tube.

found at the end of 24 hours. As a result of these experiments the author recommends the addition of an equal volume of a 5-per-cent. solution of carbolic acid to the sputum, which should be vigorously shaken up in the bottle so as to break up the lumpy coagulation. The apparatus is illustrated by the accompanying drawing. The side-tube *c* is packed with non-absorbent cotton; the arm *A* of the *U*-tube is filled with mer-

cury, the tube B is filled with the culture, when the rubber stopper holding the side-tube d and straight tube d is tightly inserted. When this is done the end of d, which serves for the escape of air displaced by the stopper, is sealed in the flame. The gas generated in B escapes into the closed arm A, displacing the mercury. To determine the CO_2 ratio, the tube B is filled to the rubber stopper. Two fermentation tubes are used. In one, the arm A is filled with mercury, and the other half of the arm is filled with a saturated solution of sodium or potassium hydrate, this being readily accomplished by inclining the U tube towards the operator. The CO_2, passing through the caustic solution, is absorbed, and the unabsorbed gas (H) is left. The ratio between the two is then determined. This apparatus is manufactured by Eimer and Amend, New York.

A New Method of applying the Rabies Test: CHAS. F. DAWSON, Detroit, Mich.

The author, in his work upon rabies, was dissatisfied with the current method of inoculating animals in the cerebrum, which involved trephining the animals, with occasional death from hemorrhage, possibility of self-inoculation and other difficulties. He has, therefore, devised a method of inoculation in which these difficulties are reduced or eliminated. The method is as follows: A bit of the brain of the suspected animal is ground in a mortar containing sterilized 6-per-cent. sodium solution, and is then filtered through sterilized cotton. Two minims of this solution are then injected on the base of the anterior cerebrum by way of the optic foramen. To accomplish this, full grown rabbits are used which are thoroughly anæsthetized with ether. A hypodermic syringe is used with a needle seven-eighths of an inch long. The inoculation is made by lifting the nictitating membrane out of the way by means of the syringe needle, and then forcing the needle upwards and backwards through the orbital tissues until it enters the optical foramen. The contents of the syringe barrel are then injected and the needle carefully withdrawn. By this means the solution is injected underneath the cerebrum and the chances of injury to the animal are much lessened. In a series of comparative tests made with this and the ordinary method, the author reaches the conclusion that the new method is fully as satisfactory as the old, and much easier to apply.

The Use of Carbolic Acid in isolating the Bacillus Coli Communis from River Water: WILLIAM B. COPELAND, Pittsburg, Pa.

The author described a method which he had devised for the purpose of separating the coli bacillus in river water, by the use of solid media. For this purpose he used Wurtz's agar, inasmuch as it could be incubated at 37° and the acid colonies were readily distinguishable by the reddening of the litmus. Inasmuch, however, as many other bacteria are present in river water, especially after a rain, which can develop at 37°, it is quite desirable to devise some means by which they may be reduced without affecting the colon bacillus. The author accomplishes this by adding to the agar two-tenths cc. of a 2-per-cent. solution of carbolic acid. Experiments showed that such addition of carbolic acid reduced the total number of bacteria about 45 per cent., while it had no effect, apparently, upon the colon bacillus. This makes it possible to determine the number of colon bacillus in water much more readily than if all bacteria are allowed to grow. By the use of this method, a study of the relation of the muddiness of river water and the number of colon bacilli was made. The result showed that, leaving out certain irregularities due to abnormal conditions, the number of colon bacilli increased with the turbidity of the water, a

relationship pointing to an increase in sewage pollution at times when the water of the river becomes turbid. The author recommends the use of carbolic acid as described in the employment of solid culture media for the determination of the number of colon bacilli present in surface waters without dilution.

A Few Experimental Data on Hypodermic Injections: S. J. MELTZER, New York City.

From two series of experiments, Meltzer arrived at the conclusions: (1) That the effect of subcutaneous injection depends to a very large degree upon the concentration of the injected fluid, and very little, if any, upon its bulk; (2) that the effect is distinctly increased by a distribution of the injected quantity over several areas. The author employed crystalloid solutions, and restricts his conclusions to this kind of liquids.

The Utility of a Supply of Live Steam in the Laboratory: H. A. HARDING, Geneva, N. Y.

The expense connected with cooking and sterilizing in the bacteriological laboratory is usually great, because of the high cost and low efficiency of gas. As a saving of time and money, the advantage of using steam, generated directly by coal, is obvious. In fitting up the bacteriological laboratory at the New York Agricultural Experiment Station, the following devices have been tried and found satisfactory: In the case of the Arnold sterilizer, a steam pipe was introduced through the wall of the passage in which the steam normally rises into the sterilizing chamber, and an elbow screwed to the end of this pipe and turned downward. With this connection, the Arnold can be brought to a temperature of 99° C. within five minutes, without any unpleasant noise or undue waste of steam. An autoclave was constructed, differing from the ordinary type in that steam was introduced from a high pressure boiler. By means of a reducing valve the steam pressure and, consequently, the temperature within the autoclave, can be held within very narrow limits. A ten-minute exposure at 120° C. suffices to render tubes of gelatin and other media sterile. Steam cups were installed, having the shape of an ordinary water-bath, except that their depth was considerably increased. A steam inlet was placed at the bottom, and a waste pipe provided for carrying off the condensation. In these cups water is heated and agar is melted much more quickly than it could be done over an ordinary Bunsen burner, and in cooking media there is no possibility of boiling over or burning. The above pieces of apparatus, together with the hot air sterilizer, are placed upon an eight-foot bench, and nearly all the heat radiated is carried off by a galvanized iron hood. These devices have been in use for nearly two years and are giving good satisfaction.

H. W. CONN,
Secretary.

WORK AND EXPENDITURES OF THE AGRICULTURAL EXPERIMENT STATIONS FOR THE YEAR ENDED JUNE 30, 1900.

THE Secretary of Agriculture has recently transmitted to Congress the annual report on the work and expenditures of the Agricultural Experiment Stations, made by A. C. True, Director of the Office of Experiment Stations. The following paragraphs are taken from the introduction to this report:

THE WORK OF THE STATIONS AS RELATED TO PRACTICAL AGRICULTURE.

In making our examination of the work of the experiment stations during the past year we have particularly inquired whether their operations are conducted with special reference to the agricultural needs of their

respective States and Territories. The results of this inquiry are embodied in the accounts of the individual stations given in this report. From these it will be seen that by far the largest part of the work of our stations has direct relation to the important agricultural interests of the communities in which they are located. The stations are, in fact, very responsive to the immediate demands of their farmer constituencies. Their greatest danger is not that they will undertake too much work of remote practical bearing, but that in the effort to meet the calls made upon them for immediate assistance they will attempt individually to cover more fields of investigation than the funds at their disposal will permit them to treat thoroughly. This temptation the stations generally are, however, resisting more successfully as their work is becoming better organized and their investigations are more carefully planned and supervised. The nature of their operations is also becoming better understood by the farmers, and the desirability of more thorough and far-reaching investigations is much better appreciated than formerly. A broader and deeper foundation of scientific inquiry is being laid each year, and there is a constant accumulation of data regarding the general agricultural conditions of the different regions of the United States. The climate, soil, water supply, native and cultivated plants, injurious insects, fungi and bacteria are being studied in more detail and with greater thoroughness than ever before. The principles of nutrition of animals and the causes of their diseases are being subjected to more elaborate and fundamental scrutiny. Methods of investigation and the improvement of apparatus for research are being given increased attention. Much of this work is done without public observation and in the intervals of other operations. Without doubt it should receive more definite recognition and encouragement. But it is cause for congratulation that so much patient labor of this character is being performed by station officers, who, as a rule, are seeking to advance the boundaries of knowledge for useful ends and are not deterred by a multiplicity of duties from giving attention to the more fundamental concerns of agricultural science. And this work is having its effect on the more practical operations of our stations. These are assuming a more substantial and systematic character and are being conducted with more definite relation to actual conditions. They have, therefore, a greater assurance of successful practical outcome. Questions relating to the introduction of plants or to the improvement of the live-stock industry in any region, for example, are now being investigated with a strict relation to the real requirements of the agriculture of that region which would have been impossible a few years ago. The present activity in plant breeding, as distinguished from the indiscriminate testing of varieties, is a good example of the raising of the level of experiment-station work as applied to directly practical ends. The plant breeder now sets definitely before him the kind of variety needed by the farmer in a given region or for a given purpose and applies all his scientific knowledge and practical skill to the production of such a variety. The notable success of some of the efforts in this direction already made are but a foretaste of much wider practical results as knowledge and experience in this line of endeavor increase. To do such work effectively there must be an almost ideal combination of science and practise. And the more we can learn definitely regarding the underlying principles, the more surely shall we be able to make successful practical applications. In such investigations science becomes more practical and art more scientific.

PROBLEMS OF STATION ORGANIZATION.

Much attention has been given during the past year to questions relating to the more perfect organization of the stations. As the stations develop, the importance of a clearer definition of the functions of different officers in administration and investigation becomes more apparent. Conditions which existed when institutions for higher education and research were established in this country have materially changed, and the old forms of organization are now, in many cases, a serious hindrance to their best development. For example, the theory on which the laws relating to the governing boards of many of the State colleges and experiment stations are based is that the board is to have the direct control and management of the institution. For this purpose it is to meet frequently, keep the details of the business of the institution well in hand, consult freely with officers of various grades and pass rules and regulations governing every operation. This may, perhaps, have been well enough when the institutions were in a formative period and trained executive officers were scarce, but to-day this theory is out of date and its application to the intricate and specialized business of our colleges and stations is highly injurious to their best interests. It works just as badly when applied to a college or experiment station as it would in the case of a railroad or a bank. The fact is that boards of control are most useful when their functions are confined to a broad, general supervision of the policy, finances and work of the institution and the choice of its chief officers. For this purpose annual or semi-annual meetings would ordinarily be sufficient, since the number of matters requiring the attention of the board should be reduced to a minimum. The best reason for the continuance of such boards is that when composed of broad-minded and successful citizens they represent the best sentiment of the community regarding these institutions, and are able to give the public an adequate guaranty for the wise and liberal management of the great interests involved in the State colleges and universities. Otherwise it would probably be best to do away with the boards and make the heads of the colleges directly responsible to some State officer of high rank. One especially annoying and unjustifiable feature of the present system is the maintenance at many of the colleges of an officer, commonly designated secretary of the board, who acts as a representative of the board in the intervals between their meetings and exercises important functions relating to the business of the institution independently of its president. There is thus divided responsibility in the daily administration, and in case of friction between the president and faculty or students often a convenient center for discontent and disloyalty is ready at hand. All the legitimate functions of a secretary of the board might easily be performed by a registrar or other officer attached to the president's office, and thus an important 'rock of offense' might be removed from the administrative systems of these institutions.

The successful college president is no longer preeminently a great scholar, but rather a broad-minded and well-trained man of affairs, understanding the requirements of modern educational and scientific institutions and able to administer the affairs and manage the personnel of such institutions. He will look to his governing board for advice and counsel on the larger matters of general policy, but he ought not to have their intervention in the details of the business. To his hands should be fully committed the administration of the whole institution, and his work should be judged with reference to its successful issue. There should be no doubt in the mind of any offi-

cer connected with the institution that he is responsible to the president for his official conduct, and that an appeal to the board can be made only in extreme cases.

The institution will naturally be divided into a limited number of departments, at the head of each of which will be placed an officer competent to plan and manage the business of the department intrusted to his charge. The amount and character of the administrative duties which these officers will be called upon to discharge will vary with the nature of the department. The agricultural experiment station is by law to be organized as a department of the college with which it is connected. It differs from the ordinary college department in being charged with the work of investigation rather than instruction and in having definite relations with a great industry for whose promotion it is especially established. Through its correspondence, publications, inspection service and association with the farming community it has an increasing amount of business not immediately relating to its investigations, but requiring special knowledge and skill for its successful discharge. To do most effective work the operations of the station must proceed in accordance with a well-matured plan which involves the cooperation of different members of the staff. So extensive and important has the business of the stations become that their proper management requires the time and energy of an executive officer, or director. In some cases it may still be possible for the director to conduct investigations in some special line or do a limited amount of teaching, but as a rule he can do little beyond attending to administrative duties. In a number of institutions prudential reasons of various kinds have led to the combination of the offices of president and director. Whatever justification there may have been for this in the past there is little excuse for it in the present. The duties of a college president are too multifold and onerous to permit his giving much attention to the special needs of an experiment station. His directorship almost necessarily becomes a nominal affair and the general business of the station is actually performed by some one member of the staff or distributed in a desultory way among a number of subordinate officers. This arrangement has not worked well and should be universally abandoned.

As regards the business of the station, the director should be clothed with a large measure of authority and consequent responsibility, should plan and supervise its work and expenditures, and control its staff to such an extent as will bring them together to work as a unit for the promotion of the station's success. The members of the staff should be directly responsible to the director on all matters relating to the station, whatever their position may be in other departments of the college, and should expect to transact station business through the director rather than through the college president or the governing board. A proper independence in the conduct of investigations, or parts of investigation, in their respective specialties, and just credit for their share in the station's operations as set forth in publications or otherwise may, it is believed, be amply secured for the expert officers of the stations at the same time that good discipline is maintained and ample provision made for united effort.

No class of men need to readjust their professional code to the modern requirements of the organization of great scientific and educational enterprises more than college professors and scientific specialists. A way must be found by which teaching and research can be conducted on a system which combines liberty with law. The old régime of the entirely independent teacher and investigator has passed away. The specialization which is simply a form of the

division of labor well known in industrial pursuits carries with it a necessity for combination of workers in educational and scientific institutions, as well as in manufacturing establishments. In a way hitherto unknown, scientific men will be called in the future to work together for common ends. No matter is of more vital importance in the organization of our colleges and experiment stations than the securing of harmonious and concerted action on the part of faculties and staffs for the common good of the institution to which they are attached. One of the greatest difficulties now attending the successful management of these institutions is the fact that while specialization has narrowed the field and outlook of the individual officer, there has not been a corresponding recognition of the necessity of readjusting the form of organization and the spirit of the worker to meet these new conditions. At no time has there been greater need of the cultivation of an earnest and enthusiastic *esprit du corps* among the rank and file of educational and scientific workers. There are many individual examples of men impressed with this lofty sentiment, but the whole body is not yet animated with it. Obviously it should especially be a virtue characteristic of men connected with public institutions. The officers of our agricultural colleges and experiment stations are public functionaries employed to advance very important public interests. With them the good of the community, as involved in the success of the enterprise with which they are connected, should be the ruling motive of action. The fame and emoluments of the individual worker should be subordinated to the requirements of concerted action for a common end. And yet in the long run it is believed the individual worker as well as the institution will profit by a loyal and self-sacrificing discharge of common duties, for union of effort will bring greater success; and whenever a college or a station is strong and flourishing, credit is reflected on every worker who has contributed to this issue.

The general considerations affecting the efficient organization of our experiment stations have thus been dwelt upon because a survey of these institutions during the past year has brought additional evidence that the problems of organization are being more generally considered than ever before. The tide is running strongly toward a more compact organization and a greater unification of the work. On the whole, those stations which have a strong organization and administration are meeting with the largest measure of success.

THE ORIGINAL WORK OF THE STATIONS.

There is also unusual interest in the discussion of problems relating to the functions of the stations and the specific duties of station officers. There is quite general agreement that each station should conduct a considerable amount of original investigation; but in what way this should be provided for and what should be its character are variously regarded. There is still great variety in the assignment of teaching and investigation to officers in different stations, and the relative amount of work of research which is left to assistants differs very greatly in different places. Considerations relating to the financial conditions of college and station still affect the assignment of work in a number of institutions. Our observation of the situation leads us to the belief that there is actually going on a widespread differentiation of the investigator from the teacher, and that this is not prevented, though it may be hindered, by the varying arrangements made at the colleges and stations. A certain number of men are more and more devoting themselves to the work of investigation, and succeeding in it. Others are just as certainly losing their interest and activity in

such work. Because a man is required to teach many hours he does not thereby become a successful teacher. The research which he is compelled to carry on during vacations and at night may nevertheless be his real mission, and it will be well if his superiors discover this. The leaving of details of research work to assistants often means that the principal has largely lost his interest in it or considers other duties more important. We are getting an increasing body of competent investigators by this process, though in too many cases their training is proceeding under untoward conditions. It will be well if boards and presidents will consider more fully the actual state of things and make as far as possible such a readjustment that the investigator will be left very largely to investigate and the teacher to teach. It continues to be a weakness of a considerable number of our stations that they are organized on too broad a scale for their resources. Too great a portion of their funds is going into salaries, leaving too little to pay the miscellaneous expenses of important investigations. Here and there only have the authorities had the wisdom and courage to confine the operations of the station within comparatively narrow lines, leaving important departments of work entirely without recognition. It is encouraging, however, to observe that where this has been done success has brought additional funds with which the scope of the station's work could be safely extended.

On the whole, the amount of what may fairly be called original investigation is, in our opinion, steadily increasing. To determine this it is not sufficient to consider simply the bulletins of the stations. These have in various ways been made more popular in form and matter. A larger amount of the more original work is being recorded in the annual reports and the records of more investigations are being withheld from publication until results of value are obtained. While there is still need of urging the advancement of the general standard of investigations, there is every reason to believe that our stations are moving onward and upward as agencies for the original investigation of agricultural problems.

THE INSPECTION SERVICE OF THE STATIONS.

The amount and variety of inspection service required of our experiment stations continue to grow from year to year. Beginning with commercial fertilizers, it now includes feeding stuffs, dairy products and other foods for man, creamery glassware, insecticides, nursery stock for injurious insects, and plant and animal diseases. For a considerable period this matter affected only the stations in the East, where commercial fertilizers were largely used, but it is now a live question in all sections of the country, since there is no region which does not have some evil against which the agricultural public is demanding protection by inspection under State or national auspices. Questions relating to the attitude of the stations toward this work are therefore engaging the attention of station officers throughout the country. Wherever this work has assumed considerable magnitude it is evident that it requires very careful organization in order that it may be conducted so as not to interfere with the work of investigation. Where the same officers are charged with both kinds of work there is constant danger that the severe routine duties of the inspection service will diminish the ability of these officers to conduct thorough original investigation. It is essential that there should be a distinct differentiation of this service from the other work of the stations as regards both funds and time of performance. Unless this is done and close supervision is exercised, the inspection work is inevitably a drain upon the resources of the station

and a hindrance to its more important operations. While our stations have from the beginning been engaged in inspection work, and this has met with increasing popular favor because of its efficient performance, it is still doubtful whether it is the best ultimate arrangement. Almost all our experiment stations are organic parts of educational institutions. As such they are essentially university departments devoted to research and to the dissemination of new knowledge. To a certain extent they may naturally and properly engage in the various forms of university extension work through their more popular publications and connection with farmers' institutes, etc. They are organized to conduct investigations on a great variety of subjects, and the scope of their work of investigation can be almost indefinitely extended as their funds increase. They do not need, therefore, to go outside of that work which would be universally considered within their rightful domain as departments of colleges and universities in order to secure a wide field of operation. On the other hand, as the range of inspection service enlarges and its duties become more onerous and complicated it becomes very questionable whether this service should be connected with our educational institutions. It is essentially a part of the police functions of the State and National Governments. It involves many questions on which sooner or later the courts will have to pass. It may even excite public attention to such an extent as to be reckoned worthy of consideration by the people in their choice of administrative and legislative officers. In many ways this kind of business is much more appropriate to bureaus of the State government than to educational institutions.

Thus far the arrangement by which much of it has been connected with the experiment stations has been largely a matter of convenience, and in many States the amount of work to be performed has been so inconsiderable that it has not seemed worth while to create special agencies for its performance. We have now reached a stage in the development of this work when it is believed that this matter should receive careful attention from the managers of our agricultural colleges and experiment stations, in order that a sound policy may be established which will provide for the best future development of these institutions. In our judgment, this would involve efforts to relieve the colleges and stations of the inspection service rather than to increase its scope at these institutions and make it a permanent portion of their work.

STATE AID TO THE EXPERIMENT STATIONS.

A number of the States continue to liberally supplement the national funds, and thus to extend and strengthen the investigation of the stations within their borders. This is done by specific appropriations for substations or special investigations, or by general appropriations for the current expenses of the colleges with which the stations are connected. Often the printing of station publications is provided for by the State. During the past year notable additions have been made to the buildings and equipment of the agricultural colleges, and the experiment stations have received much benefit from these increased facilities. At the University of Illinois a building costing $150,000 has been erected for the use of the agricultural college and experiment station. This will be thoroughly equipped with apparatus and other facilities for instruction, and when completed will form the largest single plant for agricultural instruction and research in this country. At the University of Nebraska a building costing $35,000 has been erected for the special use of the experiment station. At the Washington Agricultural College a science hall costing $60,000 has been erected, which provides

greatly improved facilities for the work of the college and station. At the Texas Agricultural College there is a new agricultural and horticultural building costing over $30,000, and at the Kansas Agricultural College an agricultural building of the same value. At the Oklahoma Agricultural College there are new chemistry and library and science buildings, and at the Virginia Agricultural College and the University of Tennessee new and commodious barns have been erected, each costing about $5,000. At the latter institution a dairy building has also been constructed. At the Agricultural College of the University of Minnesota a horticultural-botanical building costing $35,000 has been erected.

It is believed that the successful work of the experiment stations has been a large factor in arousing the attention of the public to the benefits of instruction as well as research in agriculture, and to the importance of equipping the agricultural colleges more amply and giving them increased funds for the extension of their work in both directions. It is well that this fact should be brought to the attention of legislators when appropriations for these institutions are being made. Funds are needed for the extension of investigations as well as for better equipment, and oftentimes a comparatively small sum added to the current revenue of the station will enable it materially to strengthen its work. This is so because the broad organization of our stations requires that a relatively large portion of the national funds must be expended for salaries and wages. This leaves so little for the general expenses of investigations that they can not as a rule be made very extensive. If it is desirable that particular investigations should be conducted on a somewhat extensive scale or in different localities, the State can often secure this desirable result by providing funds for these specific purposes. As regards the investigations which need to be carried on in different localities, it is, in our judgment, a much wiser policy to give the stations funds for such special investigations than to establish permanent substations, which have universally proved to be relatively expensive and unsatisfactory.

---

*THE DEVELOPMENT OF THE EXACT NATURAL SCIENCES IN THE NINETEENTH CENTURY.**

The lecture delivered by Van't Hoff, under the above title, although scarcely an hour in length, contains so much important material that a brief account of its contents cannot fail to be of interest to the readers of Science. The lecture deals only with the sciences of inanimate nature, and, therefore, does not touch any branch of the biological sciences.

Although the question of utility has had much to do with the development of many branches of science, yet the highest aim has not been reached in this way. The sciences have, then, been divided into *theoretical* and *applied*. And we must make the further division into the *general* and the *concrete* or *special* sciences.

The general sciences are dealt with first. These are divided into two classes. First, the *three fundamental mathematical sciences*, which center around the three fundamental conceptions of quantity, space and time. The science of quantity is analysis, including arithmetic, algebra and the higher analysis. The science of dimensions is geometry; while in mechanics, the science of force and movement, time enters as a factor. Second, the two *experimental natural sciences*—physics and chemistry.

Almost an unlimited amount has been accomplished in the nineteenth century in the field of the mathematical sciences. It is only necessary to mention such names

* Lecture delivered by Van't Hoff at the seventy-second meeting of the Society of German Men of Science and Physicians, in Aix-la-Chapelle.

as Abel, Cauchy, Gauss, Jacobi, Riemann, Weierstrass. The general laws of these sciences were established at the beginning of the century, and remain essentially unaltered. The great discovery for mechanics in the nineteenth century is the law of the conservation of work. Since this law lies at the very foundation of mechanics, it is of fundamental importance for the whole science. The discovery and development of this law belongs to the field of physics, yet it was not developed by physicists alone. Mayer was a physician, Joule a brewer, Colding an engineer, and Helmholtz was at that time a physiologist.

The influence of this law on mechanics was pointed out by Lagrange in two equations—the one for motion, the other for rest or equilibrium. In the light of the law that the amount of work cannot change, these two equations became relatively very simple. This law is as follows: *The total amount of work is unalterable.* It should be observed that work can have two forms, the form of movement (or kinetic energy), and the form where a weight moves a clock—where the capability of doing work is connected with the weight, therefore, with a force, (potential energy). The law should be expressed thus: *The sum of the two kinds of work is unalterable.*

We can then say, in general, of our three fundamental sciences, that at the close of the nineteenth century they rest on a foundation that is practically perfect.

If we now turn to the experimental sciences, physics and chemistry, we find that there is no sharp division between them. Recently a celebrated chemist said that Lavoisier and Bunsen were not chemists, but physicists, and to show what inherent connection exists between the two, Bunsen himself said '*a chemist who is not a physician is nothing.*'

The physicist has to do chiefly with the transformations of *force;* the chemist with the transformations of *matter.*

Turning now to physics, therefore, to the problem of the transformations of natural forces or corresponding work forms, the developments in the nineteenth century are closely connected with the fundamental conceptions that natural processes are to be referred to purely mechanical movements and forces. Since light, sound, heat, electricity and magnetism are only different forms of movement, the possibility exists of transforming these into one another. This is the first great advance in physics. It was Faraday especially who believed in the correlation of energy. This reciprocal transformation of work forms, of course, takes place in daily life in the steam engine, dynamo, etc., and from this energy heat and light can be reproduced.

The second great advance is, of course, the law of the conservation of energy, or of work, in terms of which the total amount of work remains unchanged.

A third important step was taken. If one form of work can be transformed into another and this transformation takes place quantitatively, then the question still remaining is, Which way will the transformations take place? This was answered by Carnot and Clausius in what has become the second law of thermodynamics. This is often formulated thus: Heat always flows from a warmer to a colder body. Helmholtz formulates it in terms of 'free work.'

We now consider the *last fundamental step* which has been taken—how *quickly* do transformations take place in nature? This brings us to the views in reference to the inner nature of natural processes—views which have been developed in the nineteenth century. As an example, let a local increase in pressure be produced in the air by, say, an explosion. This increase in pressure tends to equalize itself, and the excess of pressure moves through the air as

sound. From the assumption that sound is a wave movement in an elastic medium like air, Newton and Laplace calculated its velocity accurately as 330 meters per second.

That sound is a vibratory movement is not theory but fact. In other regions, however, we have only theories as to the nature of the phenomena. We have had to distinguish between matter and ether; the former consisting of very small, perfectly elastic parts, which are different for each element; the latter, a medium everywhere present, penetrating everything. The ether is the carrier of all radiation, as for example, light.

Let us trace the development of the views concerning light. According to Newton light was produced by light particles which moved with great velocity. The discovery of interference by Fresnel at the beginning of this century showed that light was a wave motion, as Huyghen's had supposed. The vibrations took place in the ether, and light moved with a velocity about one million times that of sound. In order to explain the phenomenon of polarization it was necessary to assume that the vibrations are transverse and not longitudinal.

The view that the ether is a simple elastic medium could not account for the relations between light, electricity and magnetism. Those substances which are the best conductors of electricity, as the metals, are opaque to light; while glass, which is transparent to light, does not conduct electricity. Relations such as these led Maxwell, Helmholtz and others to the assumption that the vibrations in the ether are of an electrical nature. This was the origin of the electromagnetic theory of light. In terms of this theory, light is only an electromagnetic vibration of the ether of very small period. The number of vibrations per second is about 400 billions for red and 800 billions for violet light. But there is still an infinite field for slower and also for more rapid vibrations, and here we meet with the greatest discoveries of the nineteenth century. The somewhat slower vibrations are heat rays; the somewhat more rapid are chemical rays; the still more rapid are the Röntgen rays, corresponding to the Helmholtz very rapid electromagnetic vibrations; while the very slow vibrations (about 100 million per second) are the Hertz waves. These electrical vibrations behave just like light, only they are invisible. They find application in wireless telegraphy.

The assumption is, therefore, plausible that light also is produced by electrical vibrations of the charged atoms or ions in the source of light. This is confirmed by the discovery of the Zeeman effect.

Let us now turn to chemistry. Substances like potassium and sodium, which at the beginning of the century were regarded as elementary, have been decomposed by Davy. The remaining elements have, however, maintained their elementary nature, and about 80 are now known. That an organic connection exists between the elements has been shown by Newlands, Lothar Meyer and Mendeleff. In terms of this relation new elements have been predicted and they have since been discovered by Locoq de Boisbaudran, Winkler and Nilson. These elements are, of course, gallium, germanium and scandium.

The *synthesis* of compounds has been carried very far indeed. The synthesis of urea by Wöhler broke down the distinction between the compounds prepared in nature and in the laboratory. And we can now prepare optically active substances in abundance. Synthesis has reached its climax in the preparation of the artificial dyes. Graebe and Liebermann have made alizarin. Baeyer has effected the synthesis of indigo. Ladenburg of the alkaloid coniine, while

Emil Fischer has effected the synthesis of grape sugar.

It now only remains to make artificially the enzymes and albumens. Up to the present these require the intervention of life.

The most careful quantitative study of the transformations of matter have shown that mass remains unchanged. A definite quantity of every element was, is, and will be. This recalls the law of the conservation of work, and is perhaps connected with it.

The atomic hypothesis, which was proposed by Dalton as a convenient means of explaining the laws of definite and multiple proportions, has been given new meaning by Avogadro, and Kekulé, in terms of valence, has shown how the atoms are united in the molecule. Stereochemistry has even thrown light on the arrangement of the atoms in space, and Mitscherlich has shown that there are relations between the external crystal form and the atomic composition and constitution of the molecules.

The chemistry of the nineteenth century is also characterized by the introduction of physical methods and principles, which have almost always produced marked advances, and frequently fundamental changes. Among the physical methods should be mentioned the balance, the spectroscopic methods of Bunsen and Kirchhoff, and the electrical methods, which, in the hands of Clausius and Arrhenius have led to the theory of electrolytic dissociation.

The introduction of physical principles has also accomplished much. Bertholet, Guldberg and Waage have explained the facts of chemical equilibrium, showing that a transformation only proceeds to a definite limit. They have introduced the idea of general attraction, and have shown how the active mass can be ascertained. Thomsen and Berthelot have attempted to apply the law of the conservation of work to chemical problems, and have developed the principle, which, however, does not always hold, that the heat evolved in a reaction is a measure of the affinity.

Through the united efforts of mathematicians, physicists and chemists, chemistry has, then, been placed upon a sure foundation. The second law of thermodynamics has been applied to chemical processes first by Horstmann, and then by Gibbs, Helmholtz, Duhem and others. This is, however, difficult for the chemist, since it involves a fairly good knowledge of mathematics and physics. It is, therefore, the problem of the physical chemists to give their well-established fundamental principles the simplest possible form. Something has been already accomplished.

1. The laws of dilute solutions, involving the conception of osmotic pressure, are just as simple as those of dilute gases, indeed, they are identical with them.

2. The heat evolved in a reaction determines the direction in which the equilibrium will be displaced by change in temperature. That which is formed with evolution of heat comes more and more to the front with decrease in temperature.

3. Affinity is closely connected with the conception of free work and is measured, not by the heat developed, but by the electrical work developed (electromotive force). Of these three principles, special stress is to be laid upon the importance of the last.

A very brief discussion of the *concrete* or *special sciences* follows. These include astronomy, meteorology, geography and geology.

Astronomy, by means of the spectroscope, has shown that in the spaces, so distant that it requires light many years to reach us, there is the same kind of matter as here on the earth. This includes iron, hydrogen and about twenty other elements, and these obey the same laws of reciprocal attraction as they do here on the earth. Astronomy

also calculates the history of the world in the future.

Geology gives us similar knowledge of the past, and shows that the world has not developed by sudden changes, as was formerly supposed, but that it has developed in accordance with the same laws which now reign.

Harry C. Jones.

BUFO AGUA IN THE BERMUDAS.

One of the characteristics of the fauna of the Bermudas is the scarcity of terrestrial vertebrate forms. At present there is known but a single reptile (*Eumeces longirostris*) and a single amphibian (*Bufo agua* Daudin). In 1884 Jones and Goode ('Contributions to the Natural History of the Bermudas,' Bull. U. S. Nat. Mus.) recorded no amphibian. Heilprin ('The Bermudas,' Philadelphia, 1893, p. 84) says that in 1888 he saw a few individuals of *B. agua* in the salt marshes. As far as recorded, no amphibian had been known in the colony until the introduction of this species.

The history of its introduction, as gained from an interview with Captain Vesey in July, 1900, is as follows: Captain Nathaniel Vesey (at present a member of the Colonial Parliament from the parish of Devonshire) 'about fifteen years ago' engaged the master of a vessel plying between Hamilton and Demarara, British Guiana, to secure for him some of the Guianan toads, with a view to using them to catch garden insects. The toads were brought from Demarara to Hamilton, and were carried out to Devonshire by a native, who must have purloined some of the animals, for individuals were seen near the native's home (Tuckerstown), ten miles distant, soon afterward. Captain Vesey liberated 'about two dozen' individuals in his garden, where they thrived from the first and ate many insects.

From these two centers the animal has spread until it is common throughout the colony. In its search for moist places it often gets into the cisterns, fouling the water. This fact, together with its ugly appearance and the common opinion that it is venomous, has brought it into disfavor with the inhabitants.

The porosity of the rock permits no springs, streams or ponds in the islands. The only bodies of water are several brackish tidal ponds near the shore. There are some brackish marshes the salinity of which is less than that of the ponds, but which are by no means fresh. It is in these marshes that the animal breeds. It seems to have adopted these from necessity rather than from preference, for in Jamaica (Andrews) and in Brazil (Hensel) it spawns in fresh-water pools.

The eggs are extruded 'early in the spring,' according to local report, but this must be regarded as uncertain until we have better evidence. In Jamaica spawning is said to occur in October, and in Rio Grand do Sul, Brazil, in the middle of winter (June). In July, while at the Biological Station of New York University at Hamilton, I found large numbers of young, nine to fourteen millimeters long, in the grass and on the roads near the brackish marshes. They were especially abundant just after a shower.

Bufo agua is the largest living Anuran known. The largest specimen I have seen from Bermuda was collected by the New York University Expedition of 1898 and is now in the Zoological Museum at Columbia University. It measures 155 mm. from snout to vent, and weighs 960 gm. after having been two years in a four per cent. solution of formalin.

This toad is found in South and Central America and in the warmer parts of Mexico. It has not been included in the Neoarctic fauna by either Cope or Garman. I have found no record of it west of the Andes further south than Chimbo, Ecuador (about

2° S.). The expeditions to the Andes have not recorded it above altitudes of 1,500 feet nor more than about a hundred miles back from the coast. On the east coast it is recorded as far south as the Sierras del Tandel, Argentina (38° S.) by Berg. It is found throughout Brazil and in eastern Ecuador well up towards the headwaters of the Amazon.

It has been introduced into many of the Lesser Antilles to catch insects (Herrera). In 1844, according to Gosse, it was introduced into Jamaica from the Barbadoes, where it has been used to catch field rats. It had been brought from Martinique to Barbadoes, and had been carried to Martinique from Cayenne. It appears doubtful that it is indigenous to any of the islands with the possible exception of Trinidad. Faunal lists from Cuba, Porto Rico and the Bahamas do not include it.

Bermuda is now its northern limit, both in latitude (33° N.) and in mean annual isotherm (70° F.), but this distance from the equator is exceeded on the east coast of South America both in latitude (38° S.) and in mean annual isotherm (58° F.). It is essentially a tropical and subtropical form, and I do not find record of it in the region of frost in either latitude or altitude, except for a small area in Argentina.

Bufo agua is known by various local names. The natives of parts of Brazil call it aguaquaquan, from which comes its specific name. In Jamaica it is known as a 'bull-frog.' The inhabitants are prejudiced against it throughout its range and it is killed at every opportunity.

There is a general belief that it is venomous. One Brazilian writer (Filho) says that travelers report the use of its venom in place of curari by the natives of the upper Amazon region.

Experiments show that the secretion of its cutaneous and parotoid glands, when injected into the circulation of dogs, fowls or frogs has poisonous effects, and in moderate doses causes convulsions, followed by death. There is no evidence that mere external application causes more than a slight irritation unless it reaches mucous membrane, when ulceration follows, or the cornea, which is rendered temporarily opaque.

There is not sufficient evidence to substantiate the popular belief among the natives of Bermuda that the animal can eject its secretion to a distance. There is some evidence that the secretion when taken into the digestive tract—as in the case of a dog getting it into the mouth—will cause death in a few hours, but there are no careful records of the physiological effects of the secretion beyond the fact that subcutaneous injections cause tetanic convulsions, followed by death in from one-half to two hours, according to dose.

F. C. WAITE.

UNIVERSITY HEIGHTS, NEW YORK CITY.

SCIENTIFIC BOOKS.

Le préhistorique, origine et antiquité de l'homme. Par GABRIEL et ADRIEN DE MORTILLET. 121 figures dans le texte. 3e édition. Paris, Schleicher frères, 1900. Pp. xxii + 709. Bibliothèque des sciences contemporaines.

The first edition of *Le préhistorique* dates from 1883. A second edition appeared two years later and was exhausted at the end of ten years. The value of the work, as well as the rapid growth of the science, has made a third edition imperative. Gabriel de Mortillet devoted the closing year of his life to this task, which was destined to be completed by his son and collaborator, Adrien de Mortillet.

The incorporation of an immense amount of new and valuable material, made possible by a recasting of the work, has of necessity limited its scope. The Neolithic period is left to be treated in a separate volume together with the Bronze age.

The two main divisions of the present volume are devoted to the Tertiary and early Quaternary, respectively. The authors are inclined to make the most of the evidence bearing on a

Tertiary precursor of man, devoting twelve chapters to it. The accounts of the discoveries at Thenay, Saint Prest and Puy-Courny, in France; Otta, Portugal; Yenangyoung, Upper Burma, and as core of others are faithfully reviewed.

The Calaveras skull is rejected. The deposit in which it was said to have been found is Quaternary instead of Tertiary, and the skull, besides being of doubtful origin, bears not a single mark of antiquity. Neither are the human remains from Olmo, Colle del Vento and Castenedolo, Italy, accepted as Pliocene.

The chapter on fossil monkeys closes with *Pithecanthropus erectus*, which is considered the immediate precursor of man. The authors conclude that while man did not exist during the Tertiary, there did exist precursors of man more intelligent than any of the living anthropoids.

Part second is devoted to the Early Quaternary, which, according to de Mortillet, corresponds to the Paleolithic period. The method of treatment here is less didactic than in the earlier editions, the subject matter being grouped under the following headings:

I. Industry, or Technology.
II. Man, or Anthropology.
III. Fauna, or Zoology.
IV. Flora, or Botany.
V. Geology.
VI. Geography.

The first successful attempt to establish a scientific system of relative chronology for prehistoric times was made by Thomsen of Copenhagen, in 1836. Of the subsequent writers who have contributed to the elaboration of Thomsen's triple division, Gabriel de Mortillet unquestionably ranks first. His classification is very generally accepted, and ought to be familiar to every one who wishes to keep abreast of archeological literature.

De Mortillet's system is based on the development of human industry, the successive steps of which are grouped under epochs. Following the method of nomenclature adopted by the geologist, he has given to each epoch the name of some well-known locality where the culture-stage in question is to be found in its purity.

The six epochs into which the Paleolithic period is divided, beginning with the oldest, are: Chellean, Acheulian, Mousterian, Solutréan, Magdalenian, and Tourasséan, the Acheulian and Tourasséan being regarded merely as epochs of transition.

After tracing the steps in the industrial evolution of the Paleolithic period, the authors pass in review all the discoveries of fossil human bones supposed to belong to the same period. The existence of two races is recognized —an earlier, referred to the first three epochs of the Paleolithic period and called Neanderthal, and a later, referred to the last three epochs of the same period and named Laugerian, or race of Laugerie-Basse. The Laugerian race is derived from the Neanderthal without intermixture from any foreign source. The transition may be traced in the human remains from Arcy, Eguisheim, Marcilly and Bréchamps.

Acting on the safe principle that it is better to discard correct testimony than to accept doubtful, of the 33 discoveries of human remains attributed to the lower half of the Paleolithic, 18 are discarded altogether, 4 are put in the doubtful list, and only 11 classed as authentic. Those accepted are: Neanderthal in Prussia, and Eguisheim in Alsace; La Naulette and Spy in Belgium; Tilbury and Bury Saint Edmunds, England; Denisé, Marcilly, Bréchamps, Malarnaud and Arcy, in France. The doubtful are: Canstadt, in Würtemberg; Brüx, Bohemia; Schipka, Moravia; Hamilton, Ireland. Those to be discarded are: Nagy-Sap, Hungary; Brünn and Predmost, in Moravia; Podbaba, Bohemia; Stängenäs, Sweden; Gaylenreuth, Lahr and Bolwiller, Germany; Engis, Belgium; Maestricht, Holland; Kirkdale, Victroia Cave and Galley Hill, England; Moulin-Quignon, Clichy, Grenelle, Gravenoire and Estalas, France.

Of the human remains attributed to the second half of the Paleolithic period, the authentic are: the skeletons of Laugerie-Basse, Chancelade and Sorde inférieur, all in France. A number of finds, including Cro-Magnon, Furfooz and Baoussé-Roussé are classed as Neolithic sepultures.

Ten chapters are devoted to the contemporary fauna, and three to the flora. The question of the domestication of animals is decided

in the negative. There is also no evidence that the Paleolithic hunter-populations knew anything about agriculture.

A comparative study of the fauna and flora of France and England leads to the conclusion that the British Isles were united to the continent during the early Quaternary. The Seine, instead of reaching the sea at Le Havre, flowed westward along the coast of Calvados, then north and west past the site of the present city of Cherbourg, to empty into a gulf of the Atlantic separating Cornwall from Brittany. The Somme traversed rather obliquely the Channel, and being augmented on the way by affluents from both France and England, passed between the Isle of Wight and England by way of Spithead and the Solent, where it emptied into the same gulf of the Atlantic some distance north of the Seine.

It is interesting to compare this view with that of Sir John Evans,* Mr. Codrington and the Rev. W. Fox.† The latter agree among themselves, although their conclusions were arrived at independently. They agree with de Mortillet in one respect only, viz., the river orgin of the Solent. But in their opinion, that river flowed east and not west, joining the the sea at Spithead. It was not the Somme, but a considerable stream, some of whose tributaries still exist in the small rivers which form the drainage of Dorset and Wilts.

There was also, during the Chellean epoch, a junction of Europe with America by way of the British Isles, the Faroes, Iceland and Greenland.

The volume closes with the geographic distribution of the types of industry characterizing the six epochs of the Paleolithic period. The abundance of rudely chipped Paleoliths in North America is recognized, but they are not considered as synchronous with the Chellean epoch in Europe. The Trenton terrace is referred to the same epoch as the Mousterian station of Santerno, Italy, which corresponds to 'the grand extension' of the glaciers.

In conclusion, by applying an absolute chronometric scale to the adopted system of relative chronology, the following results are obtained:

*'Ancient stone implements of Great Britain,' 2d edition, p. 690.

† *Geologist*, Vol. V., p. 452.

Chellean epoch (preglacial)	78,000	years.
Mousterian epoch (glacial)	100,000	"
Solutréan epoch	11,000	"
Magdalenian epoch	33,000	"
Total	222,000	"

To the 222,000 years of early Quaternary is to be added 'the 6,000 years since the beginning of the historic period in Egypt and a probable 10,000 years of the Protohistoric and Neolithic.' The authors believe this to be a very moderate estimate for the antiquity of man.

There is a limit to the amount of matter that can be pressed into a single volume. The one in question is exceedingly rich as it stands, being far more comprehensive than any other attempting to cover the same field. Yet many will regret that so few references were cited and that a series of maps was not incorporated. The science of prehistoric anthropology is sadly in need of cartographic enrichment. It would be difficult to conceive of a more fruitful source for such an enrichment than the combined knowledge of the de Mortillets.

We may, however, hope that the desired maps, augmented by others, will be included in the promised additional volume. May it soon appear!

GEORGE GRANT MACCURDY.

Analyse des Gaz. By M. E. POZZI ESCOT. Paris, Gauthier-Villars. 1900. Pp. 200.

Chapter I., on 'Sampling,' is by far the best in the book, being complete and well written; the writer regrets that the same can not be said of the following chapters. In the important branch of analysis by explosion not one of the later forms of explosion pipette is given. In Chapter III., on reagents, no mention is made of fuming sulphuric acid, which Winkler showed ten years ago to be the best absorbent for 'heavy hydrocarbons'; nor is any statement made of the limitations of the use of various reagents, nor of their capacity of absorption.

Chapter IV., on the analytical characters and methods of estimating the principal gases, might almost—as far as any special information about gas analysis is concerned—have been taken from any treatise on chemistry.

Chapter V., on qualitative analysis, is admirable.

In Chapter VI., on the analysis of gaseous mixtures, especially by combustion, no directions or precautions are given necessary for a successful result, nor is the treatment of the analysis of illuminating gas at all satisfactory.

Chapter VII., on gas analytical apparatus, describes in a general way a number of the important forms of apparatus.

Chapter VIII., on the calorific power of gases, is especially disappointing, the only methods given being that of Mahler—by the bomb, and by calculation, no mention being made of the excellent apparatus of Junkers.

In conclusion, the work, so far from being 'essentiellement pratique,' as reviewed in the *Comptes Rendus*, appears to be superficial, better adapted to give a general idea of the subject than for a laboratory manual.

Augustus H. Gill.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Naturalist for January begins with a list of 'Plants used by the Indians of Eastern North America,' by Lucia B. Chamberlain. The plants are arranged in alphabetic order under the name of each of the tribes considered and the uses of the plants are noted. R. W. Shufeldt has an article 'On the Systematic Position of the Sand Grouse (*Pterocletes; Syrrhaptes*),' concluding that they belong where they are usually placed, between the Galli and Columbæ. G. H. Parker discusses 'Correlated Abnormalites in the Scutes and Bony Plates of the Carapace of the Sculptured Tortoise,' concluding that there is a more intimate relation between the plates and scutes than has been generally admitted. Roswell H. Johnson describes, with outline and skiagraph illustrations 'Three Polymelous Frogs' and C. H. Eigenmann and Ulysses O. Cox consider 'Some Cases of Saltatory Variation.' James Perrin Smith treats of 'The Larval Coil of Baculites' and deduces that Baculites probably originated from *Lytoceras*, and some 'Variation Notes' are given, taken from the *Bulletin of the Société d'Anthropologie.* The Editor announces that the 'News' department will be discontinued as the same field is covered by Science more promptly, but that the record of appointments, retirements and deaths will be continued and that there will be added notices of gifts to educational institutions, all to be published quarterly.

SOCIETIES AND ACADEMIES.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY OF THE NEW YORK ACADEMY OF SCIENCES.

A regular meeting of the Section was held at 12 West 31st Street, New York, on February 4, 1901. Professor George E. Hale, director of the Yerkes Observatory, gave a lecture on 'Astronomical Photography with a Visual Telescope.' The following is an abstract:

Photography was discovered in 1837, and the first astronomical photograph was taken in 1840 by Dr. Draper of New York. It was a photograph of the moon made on a daguerreotype plate, and gave great promise of future work. Bond in 1850 made the first photograph of the stars. Rutherfurd of New York, in 1858, made some remarkable photographs of the moon, and later some star photographs.

Photography has now become so valuable in astronomy that it is applied in every department. It is not true, however, that it will displace the eye. There are certain fields where the eye will be superior to the photographic plate, but in many other fields photography has led to results that never could have been obtained by visual observation. I shall speak tonight of work done at the Yerkes Observatory with a telescope designed for visual observation. It is fortunate that this telescope was not designed for photography alone, for by the use of methods recently devised it has been possible to use it for photography and the results are not at all inferior to what they might have been on a telescope designed for photography alone.

The forty inch telescope of the Yerkes Observatory can be considered as a long camera with a focal length of about sixty-four feet. Its field of view embraces a circle in the sky of only about five minutes of arc in diameter. In photographing groups and clusters of stars this long focal length makes it possible to separate stars which would have been run together into one mass with an instrument of shorter focal length. A means of counteracting the uncor-

rected chromatic aberration has been devised by Mr. Ritchie of the Yerkes Observatory. He employs a yellow collodion film in front of the photographic plate at the eye end of the instrument, by which the blue rays are cut off. Suitable isochromatic plates, such as can be found on the market, are used. This is a very inexpensive means of using the telescope for photography. A special form of guiding apparatus to keep the star image at the same point of the plate has to be employed. On account of the unavoidable flexure of the large telescope tube, an auxiliary telescope placed parallel to the telescope tube cannot be used. The image of another star just outside the photographic plate is made use of. By means of a little eyepiece with a fine pair of cross-hairs, attached to the plate holder which is adjustable in two directions at right angles to each other, the image of the guide star is kept on the intersection of the cross-hairs during the entire time of the exposure. The photographs taken at the Yerkes Observatory in this manner by Mr. Ritchie are much finer than those taken at Potsdam with a photographic telescope.

A most important application of photography with this telescope will be the determination of the parallax of stars, which has not yet been done to any extent by photographic means.

Photographs of the small planetary nebulæ taken with this telescope show more than can be actually seen with our eyes, as in some cases a radial structure.

The instrument can also be used to study stellar spectra and stellar evolution. We can pass by gradations from the type of hot and white stars like Sirius, to the more developed and colder ones like our sun, and then to the red stars. There are two types of red stars, and by the aid of their spectra photographed with this telescope, we have detected a relationship between the two types, through the presence of carbon bands. Even in the atmosphere of the sun there is a very thin layer of carbon vapor and above this the gases of the chromosphere. In the red stars we have this carbon vapor, which is very dense in one of the types.

Another important line of work is that of measuring the motion of stars in the line of sight. Professor Frost uses the titanium line for this purpose, and has just had a new spectrograph constructed for the work.

In photographing the spectrum of Saturn with its rings, we find a faint band in the red indicating the presence of a comparatively dense absorbing atmosphere on the planet which is absent from the rings.

With the help of a spectroheliograph we are able to photograph solar phenomena. These photographs show that the mottling of the sun's surface persists throughout the minimum period of sun spots as well as through the maximum. Prominences can be photographed nearly as well with it as at times of total solar eclipse.

Mr. W. G. Levison presented a 'Note on a Cause of the Deterioration of Gelatin Photographic Dry Plates.' The author suggests that there is some emanation, probably Becquerel rays, from the pasteboard of the boxes in which the plates are packed for the market, which causes their deterioration. He found that if he cut a star from the pasteboard of a plate box and laid it on the sensitive side of a plate, the whole then being enclosed in a box for a week, when he developed the plate he obtained an image of the star. This would explain the deterioration at the edges of plates where they come nearly in contact with the box, or the deterioration due to the pasteboard separators at the edges of the plates. The author's experiments led him to the suggestion that metal boxes would be better for the plates than the pasteboard boxes. Wrapping with paraffine paper might also have the same effect.

WILLIAM S. DAY,
Secretary.

TORREY BOTANICAL CLUB.

AT the annual meeting, January 8, 1901, the Secretary, Professor E. S. Burgess, reported 15 meetings held during the year, with an average attendance of 38; 19 active members were elected. The active membership is now 238, the total membership 383; 20 papers have been presented, with addition of 26 brief notes of collections or of botanical progress.

The editor, Professor L. M. Underwood, reported a continued increase in the number of pages and of plates in the Club's publications,

including in Volume 27 of the *Bulletin*, 666 pages and 33 plates, and including Volume 9 of the *Memoirs*, with 292 pages and 9 plates. The articles printed in the *Bulletin* have numbered 63, by 48 different persons; 19 articles have contained descriptions of new species among the higher plants.

The Club voted to begin the publication of an additional monthly of about 12 pages, to include botanical notes and jottings, with reference to the local flora and to other subjects, and to bear the name *Torreya*, in honor of Dr. John Torrey, founder of the Club. Dr. M. A. Howe was made editor. The pressure of more extended technical matter upon the pages of the *Torrey Bulletin* has so far developed as to crowd out minor and more popular notes, and it was thought desirable to provide an opportunity for them by the establishment of this new journal, *Torreya*, which will be sent free to all Club members; to others at one dollar.

The officers elected for 1901 include the following: *President*, Hon. Addison Brown; *Treasurer*, Dr. H. B. Ferguson; *Recording Secretary*, Professor E. S. Burgess; *Editor*, Professor L. M. Underwood; *Associate Editors*, Dr. C. C. Curtis, Dr. M. A. Howe, Professor F. L. Lloyd, Dr. D. T. MacDougal, Dr. H. M. Richards, Miss Anna Murray Vail, Dr. N. L. Britton.

Recent papers read include Mr. J. E. Kirkwood's studies on the embryology of the Cucurbitaceae, the types selected for comparison being *Sicyos angulatus*, L., *Micrampelis lobats* (Michx.) Greene, and *Mornordica charanta*, L. These three types resemble one another in some features of their earlier development; in each case a cup-like structure is formed on the inner side of which the ovules are differentiated. In each case the normal definite embroyo-sac is a typical one. Some ovules of *Sicyos* exhibited an embryo-sac abnormally developed. Endosperm is formed soon after fertilization, and seems to have the function of digesting the tissue of the nucellus and supplying the young embryo with food material. No suspensor was found in *Sicyos*, but in *Micrampelis* and *Mornordica* it is usually formed with two or three cells.

EDWARD S. BURGESS,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE SUPPOSED TERTIARY SEA OF SOUTHERN BRAZIL.

IN an article entitled 'The History of the Neotropical Region,' published in No. 310 (Dec. 7, 1900) of SCIENCE, Dr. H. von Ihering, in order to account for certain zoogeographical facts reported by him, proposes the somewhat startling hypothesis of a tertiary sea separating two faunal sub-regions that he denominates 'Archiplata' and 'Archamazonia,' and gives the purely zoological evidence as sufficient, in his opinion, to positively establish the existence of this important geological feature. As the boundaries of these faunal sub-regions are not clearly defined the position of this sea remains doubtful, but from the context it is clear that it must have tied in with the known marine tertiary deposits of the Argentine province of Entre Rios and extended across the present mass of Brazilian highlands in such a way as to leave in the southern division a great part, if not all, of the States of Rio Grande do Sul and Santa Catharina, that is to say, in some part of the present basin of the Rio Uruguay.

Unfortunately our knowledge of the geological structure of this portion of Braziliian territory is extremely defective, but enough is known to make it certain that a presumably pre-tertiary formation stretches entirely across the region in question and thus far no geological observations or topographical features are known that suggest the slightest suspicion of any important break in its continuity. This is a formation characterized, like the triassic belt of eastern North America which it much resembles, by dykes, intercallated sheets and outflows of trappean rocks (diabase-porphyrite of Rosenbusch) of very uniform mineralogical composition, but very varied physical structure and aspect, by means of which it can readily be traced. Its geological age is undetermined, except that it is almost certainly post-paleozoic, since it overlies permian beds containing the Glossopteris flora. From this circumstance and from the strong resemblance to the above mentioned North American region, it has generally been referred to the triassic, though there is nothing to prove that it might not be cretaceous

or even tertiary. To refer it to the latter age would not, however, help the hypothesis here discussed, since there is no evidence whatever of its being of marine origin, and its northward extension well into the heart of central Brazil makes it embrace a very considerable portion of the Archamazonia faunal region of Dr. von Ihering.

The heavy trap dykes and sheets of this formation give very marked topographical features (lines of escarpments and obstructions in rivers) by which it can be traced even in regions that have not been geologically examined, and for some years I have occupied myself in tracing its distribution through such chance information and specimens as were obtainable from regions not personally known to me. Particularly valuable for this purpose was the material which for years has been accumulating in the Museum National of Rio de Janeiro and which for the region under discussion is especially important and authentic, since it contains a complete duplication of the material collected by Sellow on which Weiss' paper, the most important that has yet appeared on the geology of Rio Grande do Sul and Uruguay, was based. Without going into detail, suffice it to say that there is evidence that I consider sufficient to establish the general fact that this formation extends without a break and in the form of a great tableland, from 600 to 1,000 meters high, from near the headwaters of the Paraná in southern Goyaz and western Minas Geræs to the line of escarped hills that cross nearly in the middle, the State of Rio Grande do Sul from east to west. To the south of this line, which seems to be a giant fault, the formation lies lower and has been much denuded, so that it is frequently interrupted by areas of older rocks appearing from underneath, but thus far no evidence whatever has been presented of the occurrence of any overlying formation of marine origin.

Of special significance for our present purpose is the fact that the falls and rapids of the river Uruguay, down to the Brazilian limit and beyond, are composed of the hard traps of this formation which would thus present a barrier to the sea which in tertiary times undoubtedly occupied a part of the Argentine province of Entre Rios. The only point where the deposits of this sea are known to extend to the eastern bank of the Uruguay is near the town of Colonia, too far south to suit the hypothesis here discussed. Topographically considered, the only line in which there was a possibility of a break across this barrier is a depressed area in front of the above mentioned line of escarpments, occupied by parts of the valleys of the rivers Ybicuhy, flowing westward to the Uruguay, and Jacuhy, flowing eastward to the Atlantic. These two valleys are, however, separated by a considerable spur that unites like an isthmus the highlands of the upper Uruguay basin with those of southern Rio Grande do Sul and Uruguay. Thus far no evidence has been presented that this isthmus was ever submerged, or that the depressed portions of the Ybicuhy and Jacuhy valleys are occupied by other than fluvial deposits. It is quite possible that in secondary or tertiary times an arm of the sea may have extended into the region of the lower part of the present Jacuhy valley, but if so there is slight probability that it extended westward into those of the Ybicuhy and Uruguay, and even if such a connection be admitted it could only have been a narrow strait quite incapable of producing the 'collosal' faunal difference that it is attempted to explain. Speculation as to the probable existence of this strait is, moreover, quite gratuitous, since, if I rightly understand Dr. von Ihering, its position is entirely within his Archiplata sub-region.

ORVIILLE A. DERBY.

NOTES ON INORGANIC CHEMISTRY.

ROCK FORMATION.

AN important contribution to the study of solid solutions has been made by Professor W. Spring in the *Revue Générale des Sciences*, under the title of 'The Plasticity of Solid Bodies and

its Connection with Rock-Formation.' Experiments were carried out to determine whether under the influence of great pressure solid particles, which do not under ordinary circumstances unite, might be made to cohere. The pressure used in the experiments was about 10,000 atmospheres, and this pressure could be exerted if necessary at a temperature as high as 400°. All bodies which are plastic under pressure were found to cohere as if they had been fused, while those substances which are not malleable remained in a powder after exposure to the greatest pressures. Thus sand, calcium carbonate, alumina and oxid of iron did not cohere, and since the pressure used corresponds to a column of sand fifty kilometers in height, pressure alone can not be the cause of the formation of rocks from these materials. Metallic powders, on the other hand, cohere perfectly, which must be due to a kind of solid solution. That this is probable is shown by using mixtures of different metals, in which case alloys are formed as perfectly as by fusion. Those metals, however, which do not alloy by fusion, as lead and zinc, will not alloy under pressure. That these alloys were not occasioned by a mere mixing under pressure was shown by placing together without pressure cylinders of the same and of different metals. Even in the cold there was some adherence and, when heated to a temperature far below the point of fusion, a perfect union was obtained in a few hours. In the case of the union of different metals, an alloy was formed at the line of junction, which with tin and lead was six millimeters in thickness. Compounds were readily formed by pressure in those instances where the volume of the compound is less than that of its constituent elements, as with silver and sulphur; on the other hand, compounds which occupy more space than their constituents were dissociated by pressure. Thus copper calcium acetate was decomposed into copper acetate, calcium acetate and water. In those cases where solution is accompanied by contraction, the presence of water was found to greatly assist in the formation of solid masses from the powders, and solid carbonates were readily formed. A solution of silicic acid alone did not cause agglutination of sand, owing to the great contraction on drying, but when combined with even low pressure, solidification to a considerable extent was obtained. All these influences have played a part in rock formation.

ARSENIC IN COPPER.

LITTLE is given in chemical literature regarding the effect of small quantities of arsenic upon copper, a subject of much importance at the present day. A series of experiments is described by Ernest A. Lewis in the *Chemical News*, in which arsenic was added to a copper 99.843 per cent. pure, and the resultant metal studied photomicrographically and as to its physical properties. Malleability is not appreciably affected by small quantities of arsenic (up to 1.8 per cent.), the samples with 1 per cent. and with 1.37 per cent. rolling particularly well. The tensile strength is from 3 to 5 tons higher than that of ordinary sheet copper, the limit of elasticity is about 3 tons per square inch higher, and the elongation is not reduced. From micrographical examination, the metal appears to consist of crystals of copper, in a eutectic of copper arsenid or a solution of copper arsenid in copper. In copper intended for rolling, except that for electrical purposes, the presence of a small amount of arsenic appears to be a distinct advantage, but nothing is gained by having more than 0.5 per cent. present.

ATMOSPHERIC HYDROGEN.

AN interesting result of Professor Dewar's latest experiments, in conjunction with Professor Liveing, on the more volatile of the inert gases of the atmosphere is the demonstration that hydrogen exists free in the atmosphere in sensible proportion. There has been much question in the past as to its presence, which has not been heretofore satisfactorily proved; indeed the velocity of the hydrogen molecule renders it doubtful as to whether hydrogen would not escape from the earth into interplanetary space. On this basis there must be a continual accession of hydrogen to this planet from the interplanetary space, and hence possibly of the elements which occasion the lines of the nebular and coronal spectra. Some indications in this direction have been found in the atmospheric inert gases, and these are now being studied from this standpoint. J. L. H.

CURRENT NOTES ON PHYSIOGRAPHY.

THE CASCADE MOUNTAINS.

THE Cascade mountains are genetically described by I. C. Russell (A Preliminary Paper on the Geology of the Cascade Mountains in Northern Washington, 20th Ann. Rep. U. S. Geol. Surv., 1900, pt. II., 83–210; 10 pl., 3 maps) with such success as to give much support to rational or explanatory methods in place of the absolute or empirical methods that have long prevailed. Instead of being a sharp crested uplift, the mountains constitute a plateau, believed to have been produced by the elevation of a peneplain, but now maturely dissected. The area described, from 100 to 150 miles wide east and west, and of greater but unknown length north and south, seems to have been once a nearly flat-topped dome, 7,500 to 8,000 feet in altitude, composed of greatly disordered rock masses, whose tilted strata had been broadly truncated by long-continued erosion when the whole region stood lower. The uplift of the dome is given a late Tertiary date, because the sediments and lavas of the Columbia basin are tilted up along the eastern slopes of the elongated dome; here landslides, to be counted not by hundreds but by thousands, have occurred along the escarpments formed by the resistant lava sheets overlying weaker sediments. The granite mountains about Lake Chelan and the dissected volcano known as Glacier peak overtop their surroundings; the former are thought to owe their height not so much to resistant structure as to local uplift in excess of their neighbors. (An alternative explanation is offered, but discarded, to the effect that the ancient peneplain lay at the level of the granite summits 2,000 or 3,000 feet above the present skyline.) It is explicitly stated that no remnants of the uplifted peneplain are to be seen to-day in the form of even uplands at mountain-top height; dissection has everywhere advanced so far as to leave only sharp ridges between deep valleys. The work of the glacial period is indicated in countless cirques or corries, whose floors were so far widened that the spurs between them became sharply serrate; by numerous trough-like main valleys, with hanging lateral valleys; by lakes and moraines. The depth to which certain valleys, like that of Lake Chelan, have been eroded is taken to prove that the region stood about 1,000 feet higher than now in preglacial time; the capacity of glaciers to over-deepen their valleys not being accepted.

THE GLACIER OF MT. ARAPAHOE.

W. T. LEE describes 'The Glacier of Mt. Arapahoe, Colorado' (*Journ. Geol.*, VIII., 1900, 647–654, 2 pl.) as occupying a cirque opening to the north beneath a summit whose altitude is 13,520 feet. The front of the ice shows a stratified structure, and crevasses are believed to break its surface, while a moraine follows its front, and a stream, whitish with rock flour, issues from its base. The valley into which the cirque opens has a broad floor and precipitous sides; it holds several small lakes, sometimes in rock basins, sometimes behind barriers of waste. Evidently the existing glacier is a small affair compared with the ice stream that once stretched down the valley towards Boulder creek.

RHINE, DANUBE AND NECKAR.

THE depredations committed by the Rhine and its large branch, the Neckar, on the headwaters of the Danube, already somewhat studied by others, are clearly set forth by Penck

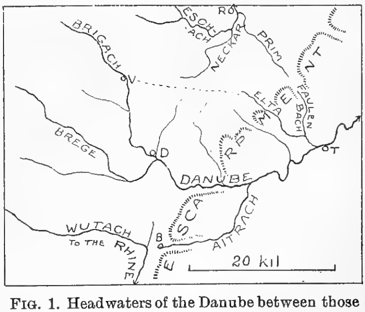

FIG. 1. Headwaters of the Danube between those of the Rhine and the Neckar. *B*, Blumberg; *D*, Donaueschingen; *R*, Rottweil; *T*, Tuttlingen; *V*, Villingen.

(Thalgeschichte der obersten Donau. *Verein f. Geschichte des Bodensees u. s. Umgebung*, 1900 ?). He shows that several ancient consequent streams flowing down the eastern slopes of the Black forest entered the Miocene sea of the

Bavarian foreland; and that as the sea withdrew the Danube was developed along its trough, engrafting into its trunk the many smaller streams that before had independent courses. As the valleys of the consequent streams were deepened, trenches were cut through the resistant strata of the white Jura, whose retreating margin was in time worn back (southeast) to form a cuesta with an infacing escarpment, while an inner lowland was opened on the weak Lias beds between the escarpment and the crystallines of the Black forest. To-day only one of the consequents (Brege-Danube) retains its course through the cuesta. The Wutach has been diverted from the Aitrach to the Rhine; the Brigach has been captured from the Elta by the Danube itself; and the Neckar has taken the Eschach from the Faulenbach. Similar changes are known for a long distance northeast of the Eschach, where the phenomena associated with the drainage of cuestas are illustrated in great variety. Penck uses the terms *Folgefluss*, *Schichtfluss* and *Gegenfluss* for consequent, subsequent and obsequent streams.

W. M. DAVIS.

CURRENT NOTES ON METEOROLOGY.

A NOTABLE STUDY OF ECLIPSE METEOROLOGY.

IN his paper on 'The Eclipse Cyclone and the Diurnal Cyclone' (*Proc. Amer. Acad. Arts and Sci.*, XXXVI., Jan., 1901, 307–318) Clayton has gone far ahead of all previous investigators of the phenomena of eclipse meteorology. Hitherto, as a general rule, we have had little more than a few scattered observations of temperature, pressure, wind direction, etc., taken during an eclipse, and tabulated, with a brief summary of the results. In his study of the meteorological data obtained in connection with the total solar eclipse of May 28th last, Clayton has derived results of far-reaching importance, which throw light on two of the largest problems in meteorology.

The meteorological changes due to the eclipse were first separated from other changes, such as the diurnal and the cyclonic, and were then plotted on maps of the United States for 8.15 and for 9 A. M., May 28th, 75th meridian time. These maps show that the winds were practically reversed in direction as the umbra moved from one side of the continent to the other, both maps showing a distinct anticyclonic circulation and an outflow of air extending from the umbra to a distance of about 1,500 or 2,000 miles. The temperature depression due to the eclipse appears on the 9 A.M. chart as an oval area. At the central portion of this area the depression exceeds 8° Fahr., and this area of greatest cold lags behind the umbra about 500 miles. A third chart was constructed by plotting the stations at their proper distances from the path of the umbra, and plotting the successive 15-minute observations at intervals of about 500 miles, the result being a synoptic chart showing the conditions observed at any station or group of stations when they were in different portions of the eclipse area. This synoptic chart indicates distinctly an anticyclonic circulation of the wind around the center of the eclipse, extending out to a distance of about 1,500 miles from the umbra. Beyond this there are indications of another ring of outflowing winds. The isotherms show an elliptical area of cold air (inner isotherm 6° Fahr.) central about 500 miles in the rear of the umbra. There was a rise of absolute and of relative humidity during the eclipse, the shape and position of the areas showing the humidity departures being very similar to those of the temperature. The pressure changes in this eclipse, and in other eclipses, show that in normal eclipses there is a central area of relatively high pressure; surrounding this a ring of minimum pressure, and beyond this, outside the edge of the penumbra, is a ring of maximum pressure.

The low temperature, the circulation of winds and the form of the pressure curve, all proclaim the development by the eclipse of a *cold air cyclone*, as described by Ferrel. Mr. Clayton points out that the eclipse may be compared with an experiment by Nature in which all the causes that complicate the origin of the ordinary cyclone are eliminated, except that of a direct and rapid change of temperature. The result shows that a fall of temperature is capable of developing a cold-air cyclone in an astonishingly short time, with all the peculiar circulation of winds and distribution of pressure which constitute such a cyclone. The fall of temperature acts primarily to cause a cyclone, and

the anti-cyclone is a secondary phenomenon—a part of the cyclone. The eclipse cyclone, to keep pace with the eclipse shadow, must continuously have formed within the shadow, and must have dissipated in the rear almost instantly. The motion may thus be considered to have a certain analogy to wave mo ion.

In the light of his discovery that the brief fall of temperature in the eclipse can produce a well developed cyclone, which accompanies the eclipse shadow at the rate of about 2,000 miles an hour, Clayton believes that the fall of temperature due to the occurrence of night must also produce, or tend to produce, a cold-air cyclone. Since the heat of day produces, or tends to produce, a warm-air cyclone, there must tend to occur, each day, two minima of pressure, one near the coldest part of the day and another near the warmest part of the day, with areas of high pressure between them due to the overlapping of the pericyclones surrounding the cold-air and the warm-air cyclones, respectively. These causes must, in the opinion of the author, produce entirely, or in part, the well-known double diurnal period in air pressure, a question which has long puzzled meteorologists and for which as yet no wholly satisfactory explanation has been offered. The surface winds at Cordoba (Argentina) and at Blue Hill are in general found to be in opposite directions, and to indicate a circulation of the wind around two cyclonic centers passing along the equator, and an outflow from high pressures half way between them.

Clayton's conclusions, which are to be presented in greater detail in a forthcoming *Bulletin of the Blue Hill Observatory*, are of the greatest interest and importance. His explanation of the diurnal variation of the barometer seems to have in it many evidences of being the best yet offered to account for this puzzling phenomenon. Meteorologists will now look forward to future solar eclipses with greatly increased interest because of the importance which Mr. Clayton has shown to be attached to eclipse meteorology. It is to be hoped that Mr. Clayton may have the time and the opportunity to extend his investigation further in connection with previous eclipses.

R. DEC. WARD.

THE MAGNETIC SURVEY OF THE UNITED STATES.

ON July 1, 1899, a special division of the Coast and Geodetic Survey Office was created by the Superintendent to take charge of the magnetic survey of the United States and the countries under its jurisdiction, which up to that time had been conducted under the supervision of the Computing Division of the Coast and Geodetic Survey. Since that date magnetic observations, namely, declination, dip and intensity of magnetic force, have been made up to December 31, 1900, at about 500 stations distributed over the United States, Alaska and the Hawaiian Islands. At most of the stations permanent marks have been established for the use of the surveyor. Special consideration has also been given to the needs of the mariner, especially in Alaskan waters, where occur places of pronounced local attraction, affecting the compasses on board ship all the way from one-fourth of a point to four points.

Special stations known as 'repeat,' or 'secular variation' stations, have also been established in different parts of the country. At these, observations will be repeated at stated intervals in order to determine the amount of secular change in the magnetic elements. It is the endeavor whenever possible to establish such stations in the vicinities of colleges and universities, as experience has shown that on college grounds we may hope for a permanency of station for a fairly long interval.

Of special state surveys mention may be made first of the completion of the magnetic survey of Maryland, which was undertaken primarily by the Maryland Geological Survey, with assistance rendered by this Bureau; second, the completion of the magnetic survey of North Carolina, conducted under the joint auspices of this Bureau and the North Carolina Geological Survey; third, the completion of the magnetic survey of West Virginia, and fourth, the completion of the magnetic survey of Iowa.

Fair progress has also been made in the establishment of the Magnetic Base Stations, where the countless variations of the earth's magnetism will be recorded photographically. Thus a temporary magnetic observatory has been in operation at Baldwin, Kansas, since

July 1, 1900, and the buildings for the primary, or principal Magnetic Base Station, located at Cheltenham, Md., 16 miles southeast of Washington, have been completed and the installation of the instruments is now taking place. Special declination readings from 7 A.M. to 4 P.M. have been made at Gaithersburg, Md., since March 22, 1900, and at Sitka, Alaska, since October 1, 1900. The sites for the Magnetic Base Stations at Sitka, Alaska, and near Honolulu, Hawaiian Islands, have been determined and preparations made for the erection of the buildings. It is intended to have these magnetic observatories completed in time for cooperation with the proposed Antarctic expeditions.

Special simultaneous observations have also been made on special days at various times, the purpose of these special observations being to determine over how large an area the variations as recorded at the Base Stations may be regarded as applying.

Various special investigations, both of an experimental and of a theoretical character, have been undertaken, and considerable attention paid to the thorough training of observers and to the proper correlation of the various magnetic instruments. During the fall of 1899 a set of Coast Survey magnetic instruments was compared with the standard instruments at the following foreign observatories: Kew, England; Potsdam, Germany; Pavlovsk, Russia, and Parc St. Maur, France.

The following publications have been issued: Appendix No. 9, giving a general report of the magnetic survey of North Carolina, and Appendix No. 10, on the magnetic work of the U. S. Coast and Geodetic Survey; both appendices appearing in the 'Report of the Survey for 1898–99.' Good progress has also been made with the new edition of the Coast and Geodetic Survey magnetic declination tables and Isogonic charts for the United States and Alaska for 1900, designed especially for the use of surveyors and mariners. There has also been issued recently Bulletin No. 41, giving a general summary of magnetic declinations and of secular variation tables in North Carolina.

T.

ADVANCE IN FORESTRY LEGISLATION.

One by one the different States are awakened to their duty in providing for the future of our forest supplies. The latest development is the introduction on January 23d of two bills into the Legislature of Michigan, which aim to place the two most needful foundation stones for the future State policy. One bill is a most comprehensive 'Forest Fire Protection Act'; the other recognizes the forest reservation policy by establishing a State Forest Reserve.

There had been previously (in 1899) created a Forestry Commission of three members, and the bills were undoubtedly drawn by that Commission with great care.

The Fire Bill is based, in general principles, upon that in existence in the State of New York, which the writer had formulated in 1885, but is improved in several directions. It provides an organization of town fire-wardens under district forest-wardens, with a single Chief Forest-Warden responsible to the Forestry Commission. It places responsibility carefully and, with rather too much prescriptive detail, tries to meet any possible case. The main improvement upon the New York State law, besides the greater coherency of the organization, is the manner in which the expense is distributed. The State pays the entire expense and then collects three-quarters of it from the counties involved, namely, one-half from the county in which the fire originated, the other half from the counties, in proportion to the area burned over in each. But, if neglect on the part of a fire-warden or a responsible county officer can be proved, the whole charge goes against that county. This provision should create a wholesome solidarity and watchfulness in the whole community.

The State Forest Reserve, or rather several reservations, are to be made up of 'delinquent tax lands' within certain districts of the southern peninsula. The area desirable to reserve is to be determined by the Forestry Commission; future tax sales are to increase this area in a similar manner, and also voluntary contributions by private individuals. A novel idea in favor of educational effort is introduced for the acquirement of additional lands

by these last means. Such grantors may, in their deed, provide 'a trust of the lands so deeded in favor of the State University or State Agricultural College, or both, whereby all income and revenue from the lands so deeded shall be paid to the beneficiary named in such deed, as a permanent endowment * * * for the purposes of its work in the line of forestry.'

The possession, care, control and management of the State Forest Reserve lands are vested in the Forestry Commission, as well as the administration of the trust lands, and ample powers and legal authority are given to the Commission to secure the greatest benefit from the Reserves. It shall not only investigate modern forestry methods, etc., but has power to cut, remove, sell and contract away any timber it deems desirable, opening the way to a rational forest management.

For the purpose of carrying on this practical forestry work, provision is made for a Chief Forest Warden with a salary of $2,000, which is rather small for a really efficient man; he is made superintendent of all Forest Reserve Lands, with a number of deputy forest-wardens, with salaries not to exceed $3.00 per day, and the fire-wardens to assist.

The conferment of sheriff's power upon the forest officers, the provision of penalties for various acts of trespass and methods of procedure are prescribed in greatest detail, and the sum of $25,000 for the first two years is set aside to carry out the program.

This legislation is undoubtedly the most comprehensive and carefully drawn which has so far been introduced in any of the states. Under it a properly constituted Commission, properly supported with appropriations, should certainly make a successful beginning in establishing a permanent State Forest Policy. A provision which would make the administration independent of annual appropriations later on, and make it rely on its income, in part at least, would be the next desirable step. The present Forest Commission, as is evident from the care with which these bills are drawn, would seem most excellently fitted for its task.

B. E. FERNOW.

SCIENTIFIC NOTES AND NEWS.

AT a meeting of the American Geographical Society, on February 20th, the Cullum Medal was conferred on Dr. T. C. Mendenhall in recognition of his services as Superintendent of the United States Coast and Geodetic Survey and as a member of the Alaskan Boundary Commission.

THE gold medal presented by the Royal Astronomical Society to Professor E. C. Pickering, director of Harvard College Observatory, on February 8th, was received by the United States ambassador, Mr. Choate, who made a speech in acknowledgment.

THE students of the University of California celebrated the 77th birthday of Professor Joseph Le Conte on February 26th. Professor Le Conte has just returned to Berkeley from a visit to Georgia.

THE Senate of the University of St. Andrews has resolved to confer the degree of LL.D. on Mr. Alexander Agassiz, of Harvard University, and on Dr. J. A. Ewing, professor of applied mechanics in Cambridge University.

MR. ALEXANDER AGASSIZ was entertained at a banquet given by the French Zoological Society on February 1st. Speeches were made by MM. Perrier, Delage and Blanchard, to which Mr. Agassiz replied.

THE University of Pennsylvania has conferred the degree of LL. D. on President Henry S. Pritchett, of the Massachusetts Institute of Technology, and the degree of D.Sc. on Rear-Admiral George W. Melville, engineer-in-chief of the United States Navy.

DR. J. K. REES and Professor H. M. Howe, of the departments of astronomy and metallurgy of Columbia University, have been decorated as Chevaliers of the Legion of Honor by the President of the French Republic for services in connection with the Paris Exposition.

AT the convocation of the University of Oxford, on February 12th, the degree of D.Sc., *honoris causa*, was conferred upon Oliver J. Lodge, LL.D., F.R.S., principal of the University of Birmingham. He was presented by Dr. Love, Sedleian professor of natural philosophy, who briefly sketched his career, his distinctions and his investigations.

THE fourth banquet of the Paris *Scientia* was given to M. Marey on January 14th. Speeches were made by MM. de Parville, D'Arsonval and Richet. M. Marey made a reply, in the course of which he called attention to the progress of the plans for the standardization of physiological instruments. It appears that the City of Paris has set aside a building where the commission may carry on tests.

THE Adams Prize for 1901, open to the competition of all persons who have at any time been admitted to a degree in Cambridge University, has been awarded to Hector Munro Macdonald, M.A., fellow of Clare, for an essay on 'Electric Waves.'

PROFESSOR A. D. MEAD, of Brown University, has been appointed a member of the Inland Fish Commission of Rhode Island, in succession to Professor H. C. Bumpus who resigned, owing to his removal to the American Museum of Natural History, New York City.

AT the meeting of the Paris Academy of Medicine on January 29th, M. Jaccoud was elected to the post of permanent secretary, vacant by the death of M. Bergeron.

PROFESSOR DAVID P. TODD, of Amherst College, will sail next week for Singapore, to observe the total eclipse of May 18th in the Island of Sinkop. Mrs. Todd will accompany the expedition to accumulate material for revising her work on 'Total Eclipses of the Sun,' a new edition of which was published by Little, Brown & Co. a year ago. A botanist, also possibly an anthropologist, will be attached to the expedition, which is expected to return in August.

WE learn from the *Electrical World* that Professor R. A. Fessenden and his corps of assistants, sent out by the Government to establish wireless telegraph stations down the coast, have completed the first installation off Roanoke Island, N. C. The station is not far from Cape Hatteras.

DR. FREDERICK A. COOK has returned to New York after having attended a meeting at Brussels of those interested in the publication of the reports of the Belgian Antarctic expedition.

PROFESSOR M. I. PUPIN, of Columbia University, delivered an address on February 13th before the Scientific Association of Johns Hopkins University, his subject being 'Recent Improvements in Long Distance Telephony.'

WE learn from *Nature* that Professor J. A. Ewing, F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which permits of the election of persons of 'distinguished eminence in science, literature, the arts or for public service.'

DR. J. W. L. GLAISHER, F.R.S., has been elected president of the Royal Astronomical Society of Great Britain.

THE following members of the Paris Academy of Sciences have been elected officers of the Bureau des Longitudes for the year 1901: *President*, M. le commandant Guyon; *Vice-President*, M. le général Bassot, and *Secretary*, Professor G. Lippmann.

THE following were elected president and members of the council of the Physical Society of London for the ensuing year at the annual general meeting held on the 8th inst.: *President*, Professor S. P. Thompson, F.R.S.; *Vice-Presidents*, Mr. T. H. Blakesley, Mr. C. Vernon Boys, F.R.S., Professor J. D. Everett, F.R.S. and Mr. J. Walker; *Secretaries*, Mr. H. M. Elder and Mr. W. Watson, Physical Laboratory, South Kensington; *Foreign Secretary*, Professor R. T. Glazebrook, F.R.S.; *Treasurer*, Professor H. L. Callendar, F.R.S., University College, Gower-street; *Librarian*, Mr. W. Watson, Physical Laboratory, South Kensington; *Other Members of Council*, Professor H. E. Armstrong, F.R.S., Mr. W. R. Cooper, Mr. G. Griffith, Mr. E. H. Griffiths, F.R.S, Mr. R. A. Lehfeldt, D.Sc., Mr. S. Lupton, Professor J. Perry, F.R.S., Mr. A. W. Porter, D.Sc., Mr. W. A. Price and Mr. R. Threlfall, F.R.S. Professor Willard Gibbs, of Yale University and Dr. Rudolph Koenig, Paris, were elected honorary fellows of the Society.

DR. JACOB GEORG AGARDH, the eminent Swedish phycologist, died at Lund, Sweden, on January 17th, aged eighty-eight years.

FRANCIS KENNEDY, PH.D., since 1898 professor of philosophy in the University of Colorado, died on February 19th of heart failure. Although but 26 years of age, Dr. Kennedy had done much research work, and

his last illness was brought on by too close study and attention to the work of his department.

THE House of Representatives has agreed to the Senate amendments to the Agricultural Appropriation Bill, reorganizing the Department of Agriculture in the direction explained in recent issues of this JOURNAL.

THE following amendment to the General Deficiency Appropriation Bill was introduced into the House of Representatives on February 21st, by Mr. Ray, of New York:

> That facilities for study and research in the Government Departments, the Library of Congress, the National Museum, the Zoological Park, the Bureau of Ethnology, the Fish Commission, the Botanic Gardens and similar institutions hereafter established shall be afforded to scientific investigators and to duly qualified individual students and graduates of institutions of learning in the several States and Territories, as well as in the District of Columbia, under such rules and restrictions as the heads of the Departments and Bureaus mentioned may prescribe.

A joint resolution to the same effect was introduced in the Senate on February 18th, by Mr. Perkins and referred to the Committee on Education and Labor.

MME AZOULAY has endowed, at the University of Lyons, a lectureship for foreign men of science. Professor Forel, of the University of Zurich, lectured on this foundation on January 27th, and Professor Schreiner, director of the observatory at Potsdam, is expected to lecture next month.

GIFTS for public libraries, conditional on their maintenance, have been made by Mr. Andrew Carnegie, to the following towns: Schenectady, N. Y., $50,000; Marion, Ind., $50,000; Galesburg, Ill., $50,000; Mount Vernon, N. Y., $35,000; Cumberland, Md., $25,000 and Port Jervis, N. Y., $20,000.

THE Royal Institution, London, has received gifts of £50 each from Sir Frederick Abel and Professor Dewar for the fund for the promotion of experimental research at low temperatures.

A TELEGRAM was received at the Harvard College Observatory, on February 22d, from Dr. T. D. Anderson, at Edinburgh, stating that a new star had been discovered by him in the constellation Perseus. The position is R. A. $3^h\ 24^m\ 24^s$ and Dec. $+ 43° 34'$. Its magnitude on February 21st was 2.7 and its color bluish-white. This star was observed at the Harvard College Observatory through clouds on February 22d. It was then first magnitude. A photograph of this region taken on February 19th showed that it was then fainter than the magnitude 10.5. This result was confirmed by photographs taken on February 2, 6, 8 and 18, 1901.

WHILE making an examination of the copper deposits in the vicinity of La Barranea, Sonora, Mexico, Mr. J. Owen, assistant to Dr. E. T. Dumble, found two deposits of torquoise. They occur in what is regarded as the equivalent of the volcanic complex described as 'Trincheras.' The deposits at Turquoise, Ariz., are in similar rocks.

MICHIGAN has long been known as a producer of copper and iron, and, more recently, as a source of salt supply for the West and the middle West. Still more recently large quantities of the secondary product of salt—caustic soda, soda ash and sodium carbonate have been sent out from the various plants in the neighborhood of Detroit. This has stimulated the search for coal, and Michigan coal, mainly from the Saginaw Valley, is now largely used. Within the past year attention has been called to the numerous deposits of marl and clay suitable for the manufacture of Portland cement, in Southern Michigan, and this interest is being rapidly developed.

THE seventy-third annual meeting of the German Men of Science and Physicians will be held this year at Hamburg from the 27th to the 29th of September.

THE French Association for the Advancement of Science will hold its annual meeting this year at Ajaccio, in Corsica, probably about the middle of September, and will be presided over by Dr Hamy.

THE *British Medical Journal* states that an Italian Society of Biology has recently been founded on the initiative of Professors Albertoni, Antonelli, Bizzozero, Bonome, Borzi Briosi, Bufalini, Camerano, Celli, Cervello, Chiarugi,

DeGiaxa, Delpino, Di Vestea, Emery, Fano, Ficalbi, Foà, Fusari, Gaglio, Giacosa, Golgi, Grassi, Guarnieri, Luciani, Lustig, Marcacci, Marchiafava, Martinotti, Mattirolo, Mosso, Pagliani, Pavesi, Pirotta, Romiti, Roster, Schrön, Stefani, Tizzoni and Todaro. The first meeting of the Society will probably be held in Rome during the coming Eastertide. The object of the Society is to promote the study of the biological sciences and everything relating to the advancement and teaching of these. The Society will publish a bulletin giving an account of its proceedings. It is divided into eight sections as follows: anatomy, physiology, pathological anatomy, general pathology, pharmacology, hygiene, zoology and botany.

THE February meeting of the Faculty Science Club of Wellesley College was held in the library of the Whitin Observatory, the paper being by Dr. Eleanor Gamble, of the Department of Psychology, on 'Certain Data for the Classification of Smells.'

THE Royal Geographical Society held a meeting on February 12th in commemoration of the reign of Queen Victoria, who was for sixty-three years the patron of the Society. The chair was taken by the president, Sir Clements Markham, who read the first paper on 'Her Majesty's Connection with the Society and Interest in Geography and on Polar Exploration during her Majesty's Reign.'

PROFESSOR WILLIAM H. BREWER, of the Yale Scientific School, lecturing at New Haven on the Antarctic Continent on February 15th, said, according to the report in the New York *Times*, that "This, the seventh and last continent of the world, which for several hundred miles extends parallel to the Antarctic circle, offering an effectual barrier to further navigation south, a New Havener had the honor of discovering. He was Lieut. Eld of the United States Navy. The memorial tablet to Lieut. Eld, which now stands in the Grove Street Cemetery, reads that he was born in New Haven in 1814 and died of yellow fever on board the U. S. S. *Ohio* in 1850. He was a member of the exploring expedition sent into the Antarctic regions by the United States Government in 1838–42 under command of Capt. Wilkes." "At 10 A.M. on January 16, 1839," so reads the tablet, "Lieut. Eld cried out 'Land.' Turning to Lieut. Reynolds who stood by he pointed out the range of icebound cliffs, along which the expedition afterward skirted for several hundred miles before it was compelled to turn back homeward. The peak which Eld first discovered was named Eld's Peak. The Antarctic continent which has never been penetrated goes by the name of Wilkes Land." The date of the tablet, which reads January 16, 1839, was discovered to be erroneous by Professor Brewer, while he was preparing this lecture. In looking through the ship's log of the expedition he found the true date to be January 16, 1840.

REUTER'S Agency gives out the following interview with Captain Joseph C. Bernier, of Quebec, regarding his proposed polar expedition: "I have two plans to lay before the Canadian Government on my return, each of which are based upon my long personal acquaintance of Arctic seas and have been approved by the best Arctic authorities. My first plan is to start by way of Behring Straits, follow the coast of Siberia and enter the ice between 165 and 170 degrees of longitude East. I shall then push north as far as the ice will permit. When my ship gets into the ice I shall then place myself in the hands of nature. If she gets into a better position than the track of the *Jeannette* I shall expect to reach the Pole, and return in between three and four years. This will not be so difficult as in the case of the *Jeannette*, because the polar basin at the present time has more openings than in past years, this being due to the changed climatic conditions. My second plan, which has already been privately submitted to the Quebec Geographical Society, is to start from Franz Josef Land with a large number of dogs and reindeer and travel during the summer to the Pole by sleighs, taking with me concentrated provisions and killing my reindeer day by day for food. Elaborate calculations have been made as to the number of dogs and reindeer required for sleighing and for food. Traveling at an average of six miles per day the journey to the Pole should occupy 150 days, at the end of which time I should still have enough provisions to return towards Spitzbergen before winter set in. The point of

the whole thing is that I intend to reach the Pole—I say I ought to get there in 150 days, but I have allowed 180 for the purpose. If I leave Franz Josef Land when the sun rises this would still leave (allowing 180 days for the journey), ten days of remaining light for me to travel towards Spitzbergen. At the expiration of this time I should put myself in winter quarters on the ice, kill the remaining reindeer for food and all the dogs not required for the rest of the homeward journey in the spring.

UNIVERSITY AND EDUCATIONAL NEWS.

PRESIDENT FAUNCE has announced that Mr. John D. Rockefeller has offered to give $250,000 to Brown University if a million dollars is collected. It will be remembered that a million dollars has already been obtained for Brown University, of which Mr. Rockefeller gave $250,000.

MRS. ANNA C. HOUGH, of Los Angeles, has offered $25,000 to the University of Southern California in case an additional sum of $75,000 be collected.

THE proprietors of the Baldwin Locomotive Works have subscribed $25,000 towards a new engineering building for the University of Pennsylvania.

A BILL has just passed the Senate granting the North Dakota Agricultural College one-fifth mill on all taxable property, thus ensuring the continuous support of the Agricultural College in place of the uncertain biennial appropriation. Plans are being prepared for a new chemical laboratory and for a science hall to be built during the present year, also for a new barn to replace the one recently destroyed by fire; loss $18,000, insurance $12,000.

THE legislature of Wyoming has made an appropriation to complete the Science Hall of the University of Wyoming and to enlarge the campus. The new building will contain the geological museum and preparation rooms, the botanical and chemical laboratories and a large lecture room. A central heating plant for all the buildings will also be built.

BEGINNING with June of the present year the University of Michigan will confer but one degree, that of bachelor of arts, on graduates from the undergraduate courses. The degrees of bachelor of philosophy, bachelor of science and bachelor of letters, which have been conferred for more than twenty years, are to be dropped. This change is brought about by the following resolution, which was passed by the literary faculty on February 18th and by the Board of Regents on February 21st:

> Beginning in June of 1901, the degree of bachelor of arts shall be conferred on any student who has satisfied any one of the four sets of requirements for graduation now in force in the department of literature, science and the arts.

THE annual commemoration day exercises at Johns Hopkins University on February 22d, were unusually impressive, as they marked the quarter centennial of the founding of the university and the formal announcement of the resignation of President Daniel Coit Gilman. The address was made by the Hon. David Jayne Hill, Assistant Secretary of State and formerly president of the University of Rochester.

THE following memorial on the subject of Coopers Hill College has, as we learn from the London *Times*, been signed by some 374 leading men of science and others interested in education:

> The correspondence regarding Coopers Hill College which has been published in the *Times* of January 3, 1901, which includes Sir Horace Walpole's letter to Colonel Ottley of December 14, 1900, and Colonel Ottley's letter of December 17, 1900, has caused a painful shock to those engaged in higher education throughout the United Kingdom, and to all who are interested in the training of engineers.
>
> This correspondence relates to the sudden and arbitrary dismissal of able and distinguished scientific teachers who have been doing duty in the college for periods of from nine to thirty years, and the value of whose past services is at the same time officially recognized.
>
> Such arbitrary dismissal is likely to affect adversely the cause of scientific teaching in the United Kingdom. It cannot fail to injure the future of the college. During the correspondence which has ensued it has become apparent that the teaching staff have no voice in the educational policy of the college and are not consulted when any change in the curriculum

is contemplated. We wish to draw the attention of the Secretary of State to this unsatisfactory state of affairs, which must militate against the success of the college as an educational center.

The sudden dismissal is action of a kind which we were not prepared to expect in any institution under the control of the British Government, and we think that the seven members of the staff who are required to retire at three months' notice are justified in asking for the inquiry into the working of the college for which they have petitioned in their memorial of December 27, 1900.

We therefore desire to express our hope that the Secretary of State for India will see his way to grant their request, and to suspend proceedings until an adequate inquiry by competent persons shall have been held.

In support of this memorial a deputation waited on Lord George Hamilton, Secretary of State for India, and addresses were made by Lord Kelvin, Lord Lister, Lord Raleigh, Sir Henry Roscoe, Professor H. E. Armstrong and Dr. G. J. Stoney. Lord George Hamilton made a reply defending the action of Colonel Ottley and the Board of Visitors. He stated that the Board of Visitors recommended the action unanimously after careful examination and that it included Sir J. Wolfe-Barry, Sir William Preece and other competent scientific men. Pensions had been granted to members of the staff. Thus Professor McLeod, whose salary was £600, received a pension of £466 and a gratuity of £185. Sir George Hamilton deprecated the agitation through the newspapers and refused a further inquiry. The following letter from Lord Kelvin is published in the *Times* for February 13th.

Sir:—Lord George Hamilton's answer to the deputation regarding Coopers Hill, yesterday, was certainly far from satisfactory in respect to the dismissal of members of the scientific staff. It gave no reason to believe that any one of those threatened with dismissal had been found in any respect incompetent or negligent in the performance of duty. Evidence brought forward by myself showed that members of the Board of Visitors were astonished to hear of seven of the scientific teachers being threatened with dismissal by Sir Horace Walpole's letter of date December 14th, and believed that the recommendations referred to in the first paragraph of that letter did not imply the supersession of more than two of the teaching staff.

Nothing in Lord George Hamilton's statement was directed to show that the recommendations for amendment in the college teaching by the Board of Visitors could not have been carried out in a thoroughly satisfactory way by the president and his present teaching staff; with perhaps some moderate change in the allocation of their duties. I had suggested in my own statement of the objects of the deputation that the official prospectus issued on January 1, 1901, which promised to the public the present staff and the present allocation of subjects, should be allowed to hold good until the end of the present session. I have ventured respectfully to repeat the suggestion to-day to Lord George Hamilton, to whom I send a copy of the present letter.

Yours faithfully,

Kelvin.

15, Eaton-place, S. W., Feb. 13.

President McKinley has appointed Capt. William Crosier, of the Ordinance Department, to succeed the late Col. Michie at West Point as professor of natural and experimental philosophy.

A chair of irrigation has just been established in the University of California, and Professor Elwood Mead, of the United States Department of Agriculture, has been called to it. Professor Mead will not resign charge of the irrigation investigation of the United States, but will take his class into the field with him during the proper months, giving up two months to lectures at Berkeley.

Elma Chandler, who has been an assistant in the botanical laboratory of the University of Michigan for the past four months, has accepted a position in the schools of Elgin, Ill.

Mr. E. J. Garwood has been appointed to the Yates Goldsmid chair of geology and mineralogy at University College, London, in succession to Professor T. G. Bonney.

At Christ's College, Cambridge University, Dr. Alfred Cort Haddon, formerly scholar of the college, university lecturer in ethnology and professor of zoology at the Royal College of Science, Dublin, has been elected to a junior fellowship.

The Isaac Newton Studentship in physical astronomy, of Cambridge University, has been awarded to Mr. S. B. McLaren, of Trinity, third wrangler, 1900.

THE CASE OF PROFESSOR ROSS.

IN view of the interest excited in academic and scientific circles by the circumstances connected with the dismissal of Professor Ross from Stanford University, we publish in full the report of the committee of San Francisco Alumni and of a committee of economists. It will be observed that they come to exactly opposite conclusions. The alumni maintain that the dismissal of Professor Ross did not infringe on the right of free speech, while the economists side with Professor Ross in his claim that he is a martyr. It may seem ungracious for men of science, who have in the past suffered for truth's sake and have won the right to free scientific investigation, not to take sides with their colleagues in sociology and economics when they unite to urge the right of academic freedom. But we can not escape the conviction that the report of the three economists is a partisan rather than a judicial document.

A distinction must be made between freedom of speech and license of speech, between the right to investigate and the desirability of using a university as a point of vantage for propagandism. Our universities should be conservative—they should

be careful in the appointment of professors and doubly careful in their dismissal. But the freedom of the individual must be subordinate to the freedom of the university. Academic freedom is the right to speak academically, and the university professor not only enjoys privileges, but also undertakes obligations.

There is no reason why as an individual Mr. Ross should not have supported by illustrated pamphlets and stump speeches free silver and Mr. Bryan in the campaign of 1896, but he should not have done so to the injury of the university. Professor Ross's methods of treating social problems may be illustrated by an extract from an article published by him the month of his dismissal. He writes in the *American Journal of Sociology:*

> A predatory minority, then, presents itself at first as a governing class that by its toils, cares, and risks contrives to draw to itself the surplus goods of the governed. But, at a later stage of development, enjoyment and control are no longer vested in the same persons. The anatomy of a parasitic organization now shows at the center certain idle enjoyers surrounded by a great number of unproductive laborers who share in their spoil, and who in return busy themselves, as retainers, mercenaries, police, priests, teachers, or publicists, in intimidating, cajoling, or beguiling the exploited majority.

As President Jordan has stated, Professor Ross has many admirable qualities and his extravagances were long born with. If we understand the matter correctly President Jordan fully concurred with Mrs. Stanford in recognizing Professor Ross's disabilities, but wished to avoid the publicity which has been brought on the university. There is no doubt but that Professor Ross has shown his unfitness for an academic position by the way he has acted since presenting his resignation to President Jordan. He said he resigned because "I am unwilling to become a cause of worry to Mrs. Stanford or of embarrassment to you." As soon as the resignation was accepted, which was done in as kind a way as possible, he does all he can to annoy Mrs. Stanford, to embarrass President Jordan and to injure the university.

The fact that Mrs. Stanford has recently given twenty-seven million dollars to the university and has retained for the present the rights that will later devolve on a board of trustees makes it somewhat easy to attack the university, but puts heavy responsibility on those who carry on such an attack. We are aware of the dangers due to the fact that many of our institutions are supported by rich men and to a certain extent controlled by them. But an impartial review of the history of university development in America shows that great tolerance has been allowed to university professors. The call of President Andrews and Professor Ross to a university supported by a State and controlled by a political party seems to be more dangerous for academic freedom than their dismissal from other universities. But on the whole there is no valid reason to criticize either our privately endowed or our State universities on the ground of suppression of legitimate freedom of speech.

REPORT OF THE COMMITTEE OF SAN FRANCISCO ALUMNI.

Your committee elected at the meeting of the association held November 20, 1900, to ascertain the confidential and other reasons

for Dr. Ross's enforced resignation begs leave to report:

That inasmuch as those interviewed, on both sides, have stipulated that the detailed information received should be treated as confidential, your committee is able to report only the ultimate facts. These are as follows:

First. Mrs. Stanford shared in the opinion general in university circles in 1896 that Dr. Ross's pamphlet entitled 'An Honest Dollar,' illustrated by political cartoons, signed by him as 'Professor of Economics in the Leland Stanford Jr. University,' and published and circulated by one of the political parties during the campaign of that year, was undignified in its form and manner of treatment, and that it was unwise in the point of the time and manner of its publication, because jeopardizing the University's right to a reputation for political non-partisanship. This incident, together with Dr. Ross's general conduct throughout that campaign, was deemed by Mrs. Stanford a symptom of unfitness for the responsible position of head of the economics department of the University.

Second. The justness of the criticism then expressed must be deemed to be conceded by Dr. Ross, since it has been admitted by him to your committee that he would not again pursue the same course under similar circumstances.

Third. Your committee is unable to find that Mrs. Stanford's objection arose because Dr. Ross's opinion differed from her own, since it is in evidence that she had at that time no opinion upon either side of the particular financial theories then in issue, and since she has not abandoned her objection to his conduct in the campaign of 1896, although his views upon the silver question thereafter radically changed.

Fourth. That from December, 1896, when Dr. Ross's chair was changed from economics to social science, until the time of his dismissal his position in the University was probational.

Fifth. That the want of confidence engendered by the incidents of 1896 was never removed from Mrs. Stanford's mind, but was accentuated by other incidents impairing her faith in his good taste and discretion. Among these your committee has found: The use of slang in his public and classroom lectures, brought to her attention by friends present, and by lampoons in the college annuals, and reports that his classroom lectures contained references derogatory to her deceased husband.

Sixth. Your committee has been unable to find any evidence that Mrs. Stanford ever took exceptions to Dr. Ross's economic teachings.

Seventh. That her ultimate demand for his resignation was not due to opinions expressed in his speeches on 'Coolie Immigration' and the 'Twentieth Century City,' but was because she deemed that her original estimate had proved correct, and that he was redisplaying, after three years of trial, those qualities found objectionable in the instance of her original action.

In passing upon the question whether Mrs. Stanford's action involved any abridgment of the right of free speech, your committee has considered very carefully the published statement of Dr. Ross, and the proofs upon which it is founded. In deliberating upon these, however, your committee has been unable to escape the force of the following facts:

First. Dr. Ross was not in the position of one able to remain in the University who chose to resign, but of one who, willing to remain, was forced to resign. His statement, therefore, necessarily attempted to tell Mrs. Stanford's reasons for forcing him out and not his own for going; hence it cannot have the probative force of his own reasons for his own acts.

Second. Dr. Ross's statement ignores the

criticism arising from his conduct during the campaign of 1896; notwithstanding that he knew at the time of publishing his statement that it was one of the operative reasons for his dismissal.

Third. The established fact that Dr. Ross desired to remain at Stanford, notwithstanding Mrs. Stanford's criticism, is inconsistent with the theory that he really regarded those criticisms as involving any abridgment of his right of free speech.

Fourth. The admission of Dr. Ross to your committee that he would not regard a university rule against the participation in politics by a university professor of economics during the progress of a political campaign as impairing the proper right of academic freedom, disposes of his contention that the criticism of his conduct in 1896 is capable of that construction.

From the foregoing facts and upon the testimony as a whole, your committee concludes that the action of Mrs. Stanford in asking the dismissal of Dr. Ross involved no infringement of the right of free speech.

REPORT OF A COMMITTEE OF ECONOMISTS.

The committee, appointed at the meeting of the economists in Detroit, December 28, 1900, to enquire into the cause of the dismissal of Professor Ross from Leland Stanford University, has earnestly endeavored to learn the facts of the case. In addition to a careful examination of the statements made in the newspapers, we have asked Professor Jordan for a full and frank statement of the causes which led to Professor Ross's removal, and have obtained the replies printed in the appendix, in which Professor Jordan declines to give specific information in regard to them. We have also in our possession copies of letters bearing upon this case from various persons, including letters from Professor Ross, as well as from President Jordan, not only to Professor Ross, but also to others.

The following facts are, we believe, undisputed:

It is customary for professors in the Leland Stanford University to be reappointed early in May of each year. Professor Ross failed to receive his annual reappointment early in May, 1900. He was, however, reappointed on June 2d. On June 5th, he handed to President Jordan his resignation as follows:

Dear Dr. Jordan: I was sorry to learn from you a fortnight ago that Mrs. Stanford does not approve of me as an economist, and does not want me to remain here. It was a pleasure, however, to learn at the same time of the unqualified terms in which you had expressed to her your opinion of my work and your complete confidence in me as a teacher, a scientist and a man.

While I appreciate the steadfast support you have given me, I am unwilling to become a cause of worry to Mrs. Stanford or of embarrassment to you. I, therefore, beg leave to offer my resignation as professor of sociology, the same to take effect at the close of the academic year, 1900–1901.

This resignation was not acted on until November 12th, when it was accepted by President Jordan in the following letter:

I have waited till now in the hope that circumstances might arise which would lead you to a reconsideration. As this has not been the case, I, therefore, with great reluctance, accept your resignation, to take effect at your own convenience. In doing so I wish to express once more the high esteem in which your work, as a student and a teacher, as well as your character as a man, is held by all your colleagues.

On November 14th, Professor Ross authorized the publication in the newspapers of a statement setting forth the causes of his resignation and its acceptance, attributing it to a dissatisfaction felt by Mrs. Stanford with his expressions of opinion on questions of public policy, particularly Coolie Immigration and Municipal Ownership of public service corporations. On the following day, President Jordan wrote Professor Ross to the effect that, in view of his published statement, it was desirable that

his connection with the University should terminate immediately.

The evidence which we have been able to obtain indicates clearly also the following facts :

1. The causes which led to the dismissal of Professor Ross existed in May, 1900.

2. Although the dismissal of Professor Ross may have been occasioned by his published statement of November 14th, his resignation was practically forced by the wish of Mrs. Stanford. This fact is distinctly stated in the report of the Alumni Committee of Investigation which report apparently has the full endorsement of the University authorities.

3. Mrs. Stanford's wishes in the matter were expressed as early as May, 1900.

4. The delay in the acceptance of Professor Ross's resignation was due to an effort on the part of Professor Jordan to overcome Mrs. Stanford's objections.

The question in regard to which we have been called upon to express an opinion is : What were the reasons which led Mrs. Stanford to force Professor Ross's resignation?

Two classes of reasons have been alleged :

1. Dissatisfaction on the part of Mrs. Stanford with Professor Ross's expressions of opinion on questions of economic policy, notably in regard to the free coinage of silver in the campaign of 1896, and more recently in regard to coolie immigration and municipal monopolies.

2. It has been asserted or suggested that Professor Ross had made statements before his classes reflecting upon Senator Stanford, that he had shown himself selfish and lacking in loyalty to the University, that he was erratic and frequently overstepped the bounds of academic propriety in the manner of giving expression to his opinions, that his publication of November 14th was a violation of confidence, and that there are facts which, if disclosed, would reflect upon his personal character.

While it is, of course, impossible for us definitely to determine what facts, or reports of supposed facts, may have weighed with Mrs. Stanford, the evidence in the possession of the committee seems to justify the following conclusions :

1. There is no evidence to show that Professor Ross gave occasion for his dismissal by any defect in moral character. On the contrary, President Jordan states in his letter of February 7th to the committee : "No ground exists for any interpretation of his dismissal reflecting on his private character."

2. There is no evidence to show that Professor Ross gave occasion for his dismissal by incompetence. On the contrary, President Jordan stated in a letter of May, 1900, that he was a 'careful thinker and a patient investigator'; 'a constant source of strength' to the University and 'one of the best teachers, always just, moderate and fair.'

3. There is no evidence to show that Professor Ross gave occasion for his dismissal by any unfaithfulness in the discharge of his duties. On the contrary, President Jordan stated in a letter of May, 1900, that 'he has been most loyal, accepting extra work and all kinds of embarrassments without a word of complaint,' and that he was 'a wise, learned and noble man, one of the most loyal and devoted of all the band' at the University.

4. There is no evidence to show that in his published statement of November 14th Professor Ross violated any confidence reposed in him. On the contrary, in a letter of December 24th, President Jordan states : "I wish after conversation with Dr. Ross to withdraw anything I may have said implying that he had knowingly used confidential material, or in any other way violated personal proprieties in making his statement."

5. Concerning the point that Professor Ross gave occasion for his dismissal by remarks derogatory to Senator Stanford, your committee finds in a statement by Mr. C. F. Lummis, in *The Land of Sunshine*, dated Christmas, 1900, the following passage:

> The precise words Professor Ross may have used I do not know, but I do know that he has stated in his classes in Stanford many things which his students understood to be reflections on Senator Stanford, and I know also that Mrs. Stanford firmly believes that he did slur her husband's memory.

In *The Independent* of February 7, 1901, Mr. Lummis repeats this charge, quoting Mrs. Stanford's reasons for his dismissal: '* * * He has called my husband a thief.'

The committee also finds that President Jordan in a letter of November 16, 1900, states:

> Mr. Keesling informs me that he and others of the alumni have heard you in your classes condemn the means by which Mr. Stanford became rich in such a way as to make it clearly a personal reference, and that some time last year Mrs. Stanford was told this by a prominent alumnus, Mr. Crothers, if I understood correctly.

In a letter of the next day, however, President Jordan retracts this by saying: "Mr. Crothers tells me that he has never mentioned the matter in question to Mrs. Stanford. I was not sure that I understood my informant to say so."

Professor Ross, moreover, at the time, unqualifiedly denied all such charges, and insisted that statements to this effect were 'a thorough-paced falsehood and a disingenuous attempt to befog the real issue.' In another place he says: "The charge from any quarter that I have ever made remarks derogatory to the character of Senator Stanford is false—absolutely without foundation." In a subsequent letter he states: "I have never referred in a derogatory way to Senator Stanford, nor have I reflected upon the manner in which he accumulated his fortune. Both my sincere respect for the Senator and my sense of the proprieties of my position forbade anything of the kind."

Moreover, that this charge could not have been a determining cause in President Jordan's acceptance of Professor Ross's resignation, is shown by the fact that in a letter of November 16th, two days after his dismissal, President Jordan says, in reference to these charges: "I never heard anything of the sort before."

6. There is no evidence to show that in the opinion of the President of the University, Professor Ross, in his utterances on the silver question, on cooiie immigration, or on municipal ownership, overstepped the limits of the professorial propriety. On the contrary, President Jordan stated in May, 1900, that his remarks on coolie immigration and on municipal ownership were in accord with the drift of public sentiment on those subjects, and that even on the silver question 'he never stepped outside of the recognized rights of a professor.'

7. There is evidence to show:

(*a*) That Mrs. Stanford's objections to Professor Ross were due, in part at all events, to his former attitude on the silver question, and to his utterances on coolie immigration and on municipal ownership; and

(*b*) That while the dissatisfaction of Mrs. Stanford due to his former attitude on the silver question antedated his utterances on coolie immigration and municipal ownership, her dissatisfaction was greatly increased by these utterances.

As to (*a*). This is shown by the fact that President Jordan at first attempted to deter Mrs. Stanford from taking any action for such reasons, stating in a letter of May, 1900: "I feel sure that if his critics would come forth and make their complaints to me in manly fashion I could convince any of them that they have no real ground for complaint." President Jordan, moreover,

intimated that to dismiss him for such reasons would be improper in the extreme, for 'no graver charge can be made against a University than that it denies its professors freedom of speech.'

As to (*b*). This is shown by the fact that not until immediately after the delivery of the coolie immigration speech did Mrs. Stanford force Professor Ross's resignation as well as by the fact that in a letter of June, 1900, President Jordan stated : "The matter of immigration she (Mrs. Stanford) takes most seriously."

In the same letter, while Mrs. Stanford's objection is declared to be due to the fact that the reputation of the University for serious conservatism is impaired by the hasty acceptance of social and political fads, it is added, that these 'local critiisms' which weighed with Mrs. Stanford 'unfortunately are based on chance matters and *obiter dicta* not at all upon your serious work.'

We have not deemed it wise to publish in full the letters upon which we have based our conclusions, but we stand ready to publish them if such a course is necessary to establish the truth in this matter.

We are aware that, owing to the failure of President Jordan to give definite replies to all our questions, there may be important facts with which we are unacquainted. On the other hand, we cannot but feel that a refusal to furnish specific information in a case of such importance—in which it is charged that the freedom of speech is at stake—is itself a fact of significance, which, to say the least, is much to be regretted.

All of which is respectfully submitted.

EDWIN R. A. SELIGMAN, Professor of Political Economy and Finance, Columbia University.

HENRY W. FARNAM, Professor of Political Economy, Yale University.

HENRY B. GARDNER, Professor of Political Economy, Brown University.

February 20, 1901.

The undersigned have examined the evidence submitted by the above committee, and believe that it justifies the conclusions which they have drawn.

APPENDIX.

DECEMBER, 30, 1900.

PRESIDENT JORDAN,
Leland Stanford Junior University,
Palo Alto, Cal.

Dear Sir: In behalf of a considerable number of economists, recently assembled in Detroit and much interested in the resignation of Professor Ross from the Leland Stanford University, we venture to address you on the subject. We understand from the public prints as well as from other sources, that Professor Ross was asked to sever his connection with the University owing to the loss of confidence in him by Mrs. Stanford, and that this loss of confidence was due primarily to the opinions expressed by him in a lecture on the subject

of coolie immigration as well as to incidental remarks on the problems of municipal ownership.

May we inquire whether, as it has been alleged in some of the Eastern journals, there are any other reasons than those mentioned for the resignation of Professor Ross, and may we hope that, if such other reasons exist, you may be disposed to communicate them to us? Many university men have been led to believe that in this case the legitimate freedom of thought without which no progress in science is possible has been discouraged. As this is a matter which concerns not a single university, but the interests of scholarship all over the country, we believe that we are not overstepping the bounds of propriety in asking information which will enable university teachers to form a just opinion on the merits of the case.

We desire to add that Dr. Ross is neither the instigator of this letter nor aware of its contents. Very truly yours,

Edwin R. A. Seligman,
Columbia University.
Henry W. Farnam,
Yale University.
Henry B. Gardner,
Brown University.

LELAND STANFORD JUNIOR UNIVERSITY,
Stanford University, Cal.,
January 7, 1901.

Professor Edwin R. A. Seligman,
Columbia University, New York City.

My Dear Sir: In response to your kind letter of December 30th, permit me to say that in view of the importance of the matter I have referred the contents of your letter to a committee of three of our professors, Vice-President J. C. Branner, Dr. J. M. Stillman and Dr. C. H. Gilbert. They are in possession of the facts and are at liberty to answer any questions which your committee may desire to ask. For reasons which will readily appear it has not been deemed advisable for us to state the reasons why Dr. Ross was dismissed. His statement to the press does not assign any of the true reasons. Very truly yours,

David Jordan,
President.

Leland Stanford Junior University,
January 14, 1901.

Professor Edwin R. A. Seligman,
Professor Henry W. Farnam,
Professor Henry B. Gardner.

Dear Sirs: Your letter of December 30th addressed to President Jordan has been referred by him to us for reply.

In your letter you say: "We understand from the public prints as well as from other sources that Professor Ross was asked to sever his connection with the University owing to loss of confidence in him by Mrs. Stanford, and that this loss of confidence was due primarily to the opinions expressed by him in a lecture on the subject of coolie immigration as well as to incidental remarks on the problem of municipal ownership."

In reply we beg to say that the dissatisfaction of the University management with Professor Ross antedated his utterances on the topics you refer to. His removal was not due primarily to what he published, said or thought in regard to coolie immigration or in regard to municipal ownership.

We can assure you furthermore that in our opinion his removal cannot be interpreted as an interference with freedom of speech or thought within the proper and reasonable meaning of that expression.

These statements are made with a full knowledge of the facts of the case.

Very truly yours,

J. C. Branner,
J. M. Stillman.
C. H. Gilbert.

January 30, 1901.

PRESIDENT JORDAN,
Leland Stanford University,
Palo Alto., California.

Dear Sir: We beg to acknowledge receipt of your letter of January 7th, as well as the letter of your committee of three, of January 14th.

You state in your letter that you are ready to answer all questions. May we venture to put the following:

1. In the committee's letter of January 14th, it is stated that the 'dissatisfaction of the University Management with Professor Ross antedated his utterances on the topics you refer to.' How can this dissatisfaction of the University management be made to agree with the statement of the President, speaking for himself and the faculty, and quoted in the public prints of November 14th as follows:

a.—Extract from a letter from Professor Ross to President Jordan: "It was a pleasure, however, to learn from you of the unqualified terms in which you have expressed to her (Mrs. Stanford) your high opinion of my work and your complete confidence in me as a teacher, a scientist, and a man."

b.—Quotation from a letter from President Jordan to Professor Ross: "I wish to express once more the high esteem in which your work as a student and a teacher, as well as your character as a man, is held by your colleagues."

2. In your letter of January 7th, you say: "His (Professor Ross's) statement to the press does not assign any of the true reasons." If the speeches on coolie immigration and municipal ownership did not constitute any of the reasons for his dismissal, why was the dissatisfaction, which in your judgment antedated these speeches, not manifested until immediately after the delivery of the same? Why was the reappointment so dubious and tardy while Professor Ross had no intimation of his possible non-appointment till May 18th?

3. In saying that Professor Ross does not assign any of the true reasons for his dismissal, do we understand you to deny the truth of Professor Ross's published statement, containing quotations from your remarks to him:

a.—That "he (Dr. Jordan) had heard from her (Mrs. Stanford) just after my address on coolie immigration."

b.—That "quite unexpectedly to him (President Jordan) Mrs. Stanford had shown herself greatly displeased with me (Professor Ross)."

c.—That "he (President Jordan) was profoundly distressed at the idea of dismissing a scientist for utterances within the scientist's own field."

d.—That "he (President Jordan) made earnest representations to Mrs. Stanford."

4. What are the real reasons for the dismissal of Dr. Ross? In your letter of January 7th, you say: "For reasons which will readily appear, it has not been deemed advisable for us to state the reasons why Dr. Ross was dismissed." Will you pardon us for saying that we fail readily to recognize any such reasons? If the reasons are that you fear to injure the personal reputation of Professor Ross, may we venture to suggest that nothing that you could do would be more calculated to injure Dr. Ross than the insinuation that there are some secret reasons which cannot be divulged. It is just because some such innuendoes have been printed in the papers that our committee addressed itself to you, in order to ascertain the true state of affairs.

While we regret to prolong this correspondence, you will readily see that unless we can give the members of the American Economic Association some explicit reasons for Professor Ross's dismissal other than those assigned by him, they will naturally adhere to the opinion based upon the statements first made in the public press. A mere denial of the truth of the statements made by him will not be apt to satisfy gentlemen who are not willing to believe that any of the parties concerned in the question would intentionally make a false statement, and facts alone will enable them

to reconcile assertions that would otherwise seem contradictory. It is for that reason that we venture again to express the hope that a more explicit answer may be given to our questions.

Very truly yours,
EDWIN R. A. SELIGMAN,
HENRY W. FARNAM,
HENRY B. GARDNER.

LELAND STANFORD UNIVERSITY, CAL.,
February 7, 1901.

PROFESSOR EDWIN R. A. SELIGMAN,
PROFESSOR HENRY W. FARNAM,
PROFESSOR HENRY B. GARDNER.

Gentlemen: Your letter of January 30th is at hand asking further information as to the reasons for the dismissal of Professor Ross. When I expressed my willingness to answer further questions I did not mean to indicate that I would enter into any circumstantial description of events leading to or following from Professor Ross's dismissal. Nor do I consider it expedient or proper to go into a discussion of extracts from my letters or conversations or of my statements or alleged statements, or those of others, as published in the newspapers. There are, however, certain assurances which it is within the privilege of the public to ask, and which it is my desire to furnish, that the public may be assisted in forming a judgment as to the position of the University upon important questions. It seems to me that I shall answer these questions best by certain plain statements which involve the important facts concerning the University. It will be necessary for you to assume my knowledge of all the facts, also that the interpretation herewith presented is authoritative from the University standpoint.

First. Professor Ross was not dismissed on account of his views on Oriental immigration nor on account of his opinion on any economic question.

Second. Professor Ross was dismissed because in the judgment of the University authorities he was not the proper man for the place he held. The responsibility for the correctness of this judgment belongs to the University authorities and to them alone.

Third. No ground exists for any interpretation of his dismissal reflecting on his private character, of which your letter seems to imply a fear.

Fourth. The judgment that Professor Ross was not the proper man for the place he held is not incompatible with my appreciation of many good qualities he possesses, nor with my wishes or efforts at any time to further his prospects. I have been neither ignorant of his professional shortcomings nor inappreciative of his good qualities. Of such appreciation Professor Ross has himself adduced several expressions from my letters.

In the hope that you may find in the above a substantial answer to the questions involved in your inquiries, I remain,

Very truly yours,
DAVID S. JORDAN.

THE SECOND MEETING OF NATURALISTS AT CHICAGO.

THE committee appointed by the meeting of 1899 issued a call for a second meeting of Naturalists at Chicago, December 27th and 28th. About one hundred naturalists were in attendance or three times the number present last year. Among those present in addition to the Chicago Naturalists were Messrs. Folsom, Hart, Holferty, Mills and Frank Smith of University of Illinois; Professors Locy and Charles Hill of Northwestern University; Needham of Lake Forest; Atherton, Birge, Juday, and Timberlake of Wisconsin; Densmore, and Grant Smith of Beloit; Lee, MacMillan and Nachtrieb of Minnesota; Osborn of Hamline; Nutting and Shimek of Iowa; Kelly of Cornell College; Thorn of Missouri; Ward of

Nebraska; Dr. Ida Hyde of Kansas; Rameley of Colorado; Eigenmann, King, Mottier and Slonaker of Indiana; Tower of Antioch College; Williams of Miami University; Grover of Oberlin; Guyer of Cincinnati; Williamson of Vanderbilt; Copeland and Parke of West Virginia; Holmes, Jennings and Pearl of Ann Arbor; Clark of Olivet; Bensley and Jeffrey of Toronto. The attendance was drawn from a much larger territory than last year and included proportionately far more botanists. Professor Nutting presided at Thursday's session and Professor Birge at Friday's.

All day Thursday papers were read at a general session and in the evening a dinner attended by forty-one persons was held at the Quadrangle Club. Friday morning was devoted to a discussion on 'State Natural History Surveys; methods, results and cooperation.' Professors Birge, Nachtrieb and Frank Smith opened the discussion in which Professors Eigenmann, MacMillan, Nutting, Ward, Cowles, Hartzell and others also took part. The papers of Professors Birge, Nachtrieb and Smith will appear in SCIENCE. As a result of an eloquent plea for higher ideals of university and college administrators with reference to research, made by Professor Loeb at the dinner, the following committee on the relations of colleges to research was appointed: Professors Loeb, Cowles, H. M. Kelly, MacMillan, Nachtrieb, Nutting and Ward. As the relation of the Naturalists' meeting at Chicago to the American Society of Naturalists was still undefined no definite organization was effected but the following committee on a meeting in 1901 was appointed: Professor S. A. Forbes, University of Illinois, Chairman; W. A. Locy, Northwestern University; Conway MacMillan, University of Minnesota; D. M. Mottier, University of Indiana and C. B. Davenport, University of Chicago; the last as Secretary.

On Friday afternoon separate sections in botany and zoology were organized for the reading of papers. Abstracts of the papers read at the meeting follow:

On the Absorption of Water by Frogs: HENRY H. DONALDSON.

A group of frogs that had been dried for hours was weighed and it was shown that through exposure to the air of the laboratory in a dry dish, they had lost 14 per cent. of their body weight. These frogs were at once placed in a dish containing water about 1 cm. deep, and in 24 hours had regained nearly the entire weight lost by drying. This gain in weight was attributed to the absorption of water through the skin, and the fact that frogs never took water by the mouth was emphasized. Both the loss and the absorption of water are more rapid during the summer season than in the period of hibernation. The general influence of this capacity of the frog to lose and gain water readily was pointed out, and the evidence adduced that the amount of water normal to the spinal cord varied with the season of the year, being high from the last of May to the first of July, a season during which growth probably occurred, and gradually diminishing from this period to the time of hibernation.

Heterogeneous Induction in Tadpoles: E. B. COPELAND.

In water deficient in oxygen tadpoles swim like fish, with their noses to the surface. This behavior, though, is not a direct search for oxygen, but a manifestation of negative geotaxis. If the water is covered with oil they stick their noses into it and keep them there, or in full and closed glass vessels they keep their noses against the glass above. When in the greatest need of oxygen they remain, as under ordinary conditions, negatively phototactic. Their behavior with reference to gravity is not the result of their own experience.

The Reactions of Hydra to the Electric Current: RAYMOND PEARL.

An expanded hydra with the long axis of the body at right angles to the direction of the current becomes oriented with the head towards the anode shortly after the current is made. This orientation is brought about by a contraction at a point just above the foot on the anode side of the body. The bending of the body at this point is very slow, but continues until the long axis is parallel to the direction of the current and the head is towards the anode, *i. e.*, until the Hydra is oriented. The details in the mechanism of this orientation are modified with increasing intensity of current, but the essential factor, namely, contraction on the anode side, is constant except when the very strongest currents are used. On making a current of such strength as practically to kill the hydra, immediately there occurs a slight muscular spasm on the *kathode* side of the body. If at the time of making the long axis of the body is already parallel to the direction of the current and the head is towards the anode, the animal contracts immediately and violently, while in the opposite position there is no immediate contraction. The contraction phenomena of the tentacles are different from those of the body as a whole.

The Effect of some Climatic Factors upon the Color and Color-patterns of Insects: W. L. TOWER.

The effect upon variations of color and color patterns of the environmental factors, temperature, moisture, food and light has been investigated experimentally during the past two years. Coleoptera and Lepidoptera have been used and have been subjected to the conditions of the experiments throughout the life cycle. The results represent more nearly the effects these factors produce as they act in nature, than when applied at one stage alone, *i. e.*, pupal. The most extensive work has been done with *Leptinotarra decem-lineata* Say, and these results will be published soon.

Additional Remarks on Cave Salamanders: C. H. EIGENMANN.

The types of a new cave salamander from Missouri were exhibited, also a specimen of the bleached cave salamader, *Typhlotriton* from Marble Cave, Mo. The latter had been kept in the light for a few weeks and showed a marked increase of pigment in its chromatophores. The amount of bleaching in cave animals is directly proportional to the degree of degeneration reached by the eye. Whether there is any connection between the two is under investigation. Epigean species, if living in caves for any length of time, become bleached. The presence or absence of color is, then, due in the first instance to the environment. The cave fishes of Indiana no longer respond to the change in their environment, as the salamander does, and even the young of the cave fishes, if reared in the light, do not take on color. The bleached condition has become hereditary in their character. In the establishment of the bleached condition, which in the first case is an individually acquired character in the hereditary mechanism, we have an instance of the transmission of the direct effect of environment.

The Relation between Base-leveling and Plant Distribution: HENRY C. COWLES.

The local distribution of plants depends largely upon the character of the topography. The topography constantly undergoes well-known changes, hence the vegetation must change. In other words the ecological study of plants and plant societies should be based on dynamical principles. The growth of a river well illustrates these principles; first, there is a xerophytic gully, then a ravine, whose slopes soon become mesophytic. As the valley widens the

slopes become xerophytic. In the valley itself a flood plain eventually develops which has at first a hydrophytic and finally a mesophytic flora. There are local digressions from this history, but in general it may be said that mesophytic flood plain vegetation is ever on the increase and may be regarded as the ultimate type.

Base-leveling and its Faunal Significance, with Illustrations from Southeastern United States: CHARLES C. ADAMS.

Attention was called to the necessity of correlating the influences of the base-leveling processes with the distribution of habitats, and especially the importance of a knowledge of river histories in the study of fresh-water faunas. An outline was given to illustrate the principles involved in the reduction of an elevated country to sea-level. By the growth of valleys there is a decrease of uplands, a premium being placed upon those forms whose habitat is increasing in area; thus tension lines are produced. There is a definite succession of forms advancing up a valley, and thus in descending a river one may find a rough recapitulation of the types of faunas which occupy a stream during its ideal history. With a reduction of divides, rapid water, upland faunas are the first to mix. Attention was attracted to the importance of the base-leveling factors about two years ago, in connection with the studies on the *Pleuroceridæ.* The anomalous distribution of this family in the Tennessee and Coosa-Alabama river systems was at once explained upon learning, at that time, that formerly the Tennessee river from Chattanooga flowed to the Gulf viâ the Coosa-Alabama system. Valley faunas are isolated by uplands and *vice versa.* The Cumberland Plateau and the Smoky Mountains have been isolated by the Tennessee valley and consequently have peculiarities in their fauna. The land shells, according to Pilsbry, of the Cumberland Plateau have about 20 characteristic species or varieties and the Smoky Mountains about 25. The geologists (Woodworth) have had a better appreciation of these factors. Students of distribution should give more importance to habitat as a dynamical factor in their study of faunal problems. This will lead to the study of faunas in a comparative and genetic way.

Demonstration of certain Features in the Reactions of Infusoria: H. S. JENNINGS.

Demonstrations by means of the projecting microscope and stereopticon, of the reactions of unicellular organisms toward carbon dioxide and various other chemicals. The demonstrations were essentially the same as those described in SCIENCE for January 11, 1901, pp. 74, 75.

On certain Methods by which Organisms Regulate their Movements with Relation to the Position of External Objects acting as Stimuli: H. S. JENNINGS and RAYMOND PEARL.

The paper showed the biological significance of the revolution on the long axis, with the resulting spiral path, which is a feature of the swimming of many lower organisms. These organisms usually tend to swerve toward one side, and thus to swim in circles; the revolution on the long axis converts this circular path into a spiral one, and thus permits an unsymmetrical organism to follow a course which is in effect a straight one. The paper gave an account of very simple mechanisms for turning to or from a source of stimulus in a number of organisms, Rotifera, ctenophores, flatworms, and the earthworm.

Experiments in Artificial Parthenogenesis: J. LOEB. Already described in SCIENCE.

Cœnogametes: DR. B. M. DAVIS.

The peculiar multinucleate gametes of the *Phycomycetes* were considered and the results of Dr. Stevens' studies and the writer's on Albugo were described. These

peculiar structures (Cœnogametes) are likely to be found far more generally in this group of fungi than has been imagined, and the subject takes on considerable biological interest.

The fusion of multinucleate gametes results in the pairing of the sexual nuclei and consequent union, two by two, giving about half as many fusion products as the original number of sexual nuclei. The phenomenon recalls the conjugation of swarm spores in water outside of the parent gametangium, the difference being that here the sexual elements are retained in the parent structure.

The origin of these cœnogametes is uncertain. It was suggested that they may have come from a much simpler condition of sexual organs than has been supposed. They are possibly derived from a gametangium of the lowly type presented in several algal groups where motile gametes are discharged into water. An alternative hypothesis demands that the behavior is exceptional and derived from a condition of heterogamy. But a serious objection will be raised to such a view if the cœnogametes, as seems likely, are found to be far from exceptional among the *Phycomycetes*.

Early Development in certain Hybrid Species: W. J. Moenkhaus.

In more than 20 crosses among fishes, there was not a single failure of impregnation, although some of them were between species of different orders. The per cent. of impregnation ranged from 1 to 95. The highest per cent. may be between the most distantly related species. Eggs normally impregnated complete the segmentation stages. Two crosses and their reciprocals largely went to closure of the blastopore with the main axis of the embryo apparently normally formed. Only the closely related species went far enough to hatch. The cross between brook trout ♀ and lake trout resulted in 'fingerlings,' a large per cent. of which had the caudal peduncle aborted and many had the anal fin wanting.

The *rate* of development was in all cases that of the egg species or slower. The conjugation of the pronuclei is normal. In the first cleavage spindle of the cross between *Fundulus heteroclitus* ♀ and *Menidia notata* the ♀ chromosomes appear as long, slightly wavy rods, and the ♂ chromosomes as short, comma-shaped rods. This difference is maintained to the 16-celled stage, as far as they have been followed. In the cross between *Fundulus heteroclitus* ♀ and *Ctenolabrus adspersus* the ♂ chromosomes are scattered along the spindles. This condition obtains as far as the third cleavage and there is some evidence that some or all of the ♂ chromatin may be lost in the course of development.

Abnormalities on the Horny Plates of the Turtle, Chrysemys marginata: S. E. Meek. (Will appear in the *American Naturalist*.)

Variation in the Madreporic Body and Stone Canal of Asterias vulgaris: Gertrude C. Davenport.

A number of cases of multiple madreporic plates were observed in the starfish *Asterias vulgaris*, of Cold Spring Harbor. This multiplicity may occur either in one interradius, in several of them, or in all. Thus three plates were observed in one and the same interradius and in another case five. In one case five plates were observed in one interradius, and one in another of the same starfish. A six-rayed individual had one madreporic plate in each of the six interradii. When only one madreporic plate is present it may be lobed or partially divided by cross seams into 2, 3, 4, 5 and 6 parts.

The multiplicity of plates may or may not be accompanied by a multiplicity of stone canals. A group of four plates had only one canal, while one of five had two.

In European starfishes multiple madreporic plates occur in those forms that multiply by self division. Hence they are the result of regeneration. This multiplicity is more frequent in starfishes, normally or abnormally, with more than five rays. The Cold Spring Harbor starfishes very freely cast off their arms when handled. Do they practice autotomy in nature?

Some Variations in Lucanus placidus, Statistically Examined: ELIZABETH B. MEEK.

The mandibles of the stag beetles, especially in the male sex, are extraordinarily developed and armed with teeth or projections. These vary greatly in different species and in different individuals of the same species; correlative with these differences there are extreme differences in body length. In some species the variations are so great that dimorphism exists, resulting in a division into high and low males. A quantitative expression for these differences in size and form in *Lucanus placidus*, was sought, with the following results: The average body length is .4 mm. greater in the male than in the female and the coefficient of variation is greater; this is also true of the mandibles where the average length is 2 mm. greater in male than female. The coefficient of correlation between length of body and length of mandible is .2 greater in the male than female. The teeth on the mandibles may be termed primary and secondary. A large or primary tooth is invariably present on the mandibles of both male and female, but there is great variation in position, form and number of the secondary teeth even on the same pair of mandibles, as one cutting edge may have only one while the opposite has any number of secondary teeth. Average number of teeth on mandible of male is 4 more than on female. There is a correlation between the number of teeth and length of mandible which is .2 mm. higher in males than females. Number of spines on fore tibiæ varies from 6 to 11, with an average of 4 more upon tibiæ of males than females.

It is thus found, as should be expecte d that variation is greater in the males than females. Also that there is no dimorphism in length of bodies, mandibles nor tibiæ. There is positive skewness in the body lengths and negative in the mandibles, but just what this may mean I am, at present, unprepared to say, as this study is preliminary to a more complete one of the variation and distribution of representative Lucanidæ in the United States.

The Place-mode of Daphnia pulex, for Cold Spring Harbor, Long Island: H. M. KELLY.

The results of measurements of many organs on a large number of individuals.

Contributions to the Biological Interpretation of Skew Variation: C. B. DAVENPORT.

The paper presented conclusions based on a study of many cases of skew variation in organisms.

The Genetic Development of the Forests of Northern Michigan: H. N. WHITFORD.

This article will appear in full in an early issue of the *Botanical Gazette*. The factors controlling the distribution of plant societies and formations are divided into three groups—climatical, ecological and historical. These are discussed with special reference to their effects on forests.

A succession of plant societies on four sets of physiographic formations is recognized. In each instance the climax society is the deciduous forest.

In the sand series the stages are beach, heath, coniferous forest and deciduous forest. Here a controlling factor is the accumulation of humus. The pre-Cambrian rocks of the Marquette region offer an admirable field for the stages in the life-history of rock societies. Here not only humus, but inorganic soil, has to be accu-

mulated before the deciduous forest appears. Swamp series and clay soil series show similar stages before the climax deciduous forest society is made possible. In every instance there must be a coniferous or poplar-birch forest before the maple-beech deciduous forest, for in that way only can shade conditions be obtained for the protection of maple and beech seedlings.

Application of the Quantitative Method to the Dynamical Study of Plant Societies: HENRY C. COWLES.

The vegetation in the vicinity of Chicago is being systematically mapped from an ecological standpoint, topographic maps being used as a basis for work. By means of accurate mapping and recording of field observations at selected points, it is hoped that sets of data may be obtained showing the rapidity of encroachment of one plant society upon another. By means of photographs taken at one-year intervals considerable change has been found in the dune region, and this suggests the desirability of a similar study for other plant societies.

An Anatomical Classification of Vascular Plants: E. C. JEFFREY.

The use of the skeleton in the phylogenetic study of plants has been almost entirely neglected. In recent years paleobotanists have done something to remedy this defect, but they have been without the important aid furnished by the study of development. The present article, illustrated by a large number of photographs of the vascular skeleton of living and fossil plants, and especially the developing skeleton of extant groups of plants, is intended to show that there are a number of absolutely constant and characteristic anatomical criteria.

Stomata of some Liliaceæ: E. P. COPELAND.

The stomata of Liliaceæ are very diverse in structure, but most of them are well built to open and shut. Many of them (*Uvularia, Smilacina, Polygonatum, Dracœnam, Smilax, et al.*) are so circular in surface view that an increase in turgescence would not open the pore if the walls at the ends of the guard cells were not much more rigid than those of their backs. This rigidity is secured by special local thickening, or by the mode of insertion of the walls of adjacent cells. The stomata of *Medeola* are also circular, but the backs are strengthened by folds in the wall. The pore opens by an increase in the depth of the guard cells, *i. e.*, at right angles to the surface of the leaf. It is a perfect development of what has been called the Mucinus type of stoma.

Methods of Plankton Measurement: JACOB REIGHARD and HENRY B. WARD.

The paper presented a brief review of methods introduced by Hensen, and used by a number of observers for computing the amount of plankton obtained by hauls of a vertical net, and of the calculations on theoretical and experimental bases given by Hensen, Reighard and others for determining the coefficient of the net, *i. e.*, the fraction of the column of water which actually passes through it. The authors propose to determine the coefficient by actually measuring the amount of water passing the mouth of the net. This is to be accomplished by means of a three-vane meter suspended in the axis of the net opening a short distance inside its upper rim. By means of an electric pen register the revolutions of meter are recorded on a tape, and parallel to them, both the starting and stopping signals, and the time record from the chronometer, from which it is possible to calculate the number of revolutions in the time of the haul, or the time or revolutions in any desired fraction of the haul. The difficulties and errors in the management of the apparatus were discussed, together with the means for detecting them. The rating of the meter by two different methods was

also considered, and the coefficient of the net shown in the plottings of the rating experiments. Experiments without a meter were also used to demonstrate that the efficiency of Hensen's net had not been diminished, but rather increased by the addition of the brass cylinder and meter at the net opening.

As prominent factors in determining the efficiency of the net were mentioned the size of the orifice, and the ratio between the area of the orifice and the area of the filtering surface. Various details in improvements of apparatus were mentioned, and the laboratory of the United States Fish Commission at Put-in-Bay, together with the steamer and apparatus used and the records obtained, were illustrated from lantern slides.

A New Method of Reproduction in Tubularian Hydroids: C. C. NUTTING.

The medusæ of *Hybocodon prolifer* were found to be reproducing by means of actinules formed on the manubrium. The process of development of the actinules was described, and the intergradation between this process and the production of actinules in the gonophores of ordinary tubularians was traced through a series of forms including *Tubularia spectabilis* (Agassiz), *Tubularia cathouyi* Ag., and *Corymorpha pendula* Ag. The paper was illustrated by charts prepared by the author.

Remarks on the Distribution of Hydroida on the North Pacific Coast; C. C. NUTTING.

The basis of this paper was a study of the Hydroida of the Harriman Alaska Expedition. The division of the Pacific Coast fauna made by Dall in 1876 was found to be untenable in the light of our present distribution of the hydroids. It was shown that there was no marked differentiation between his Aleutian and Oregonian faunæ, on the one hand, and that the Oregonian fauna does not extend to Monterey, California, on the other. The facts seem to indicate a division between an Alaskan and a Californian province just south of Puget Sound. The author pointed out that this arrangement was only tentative, and that the distribution of other groups of marine animals of that region would be necessary before any conclusive statement could be made.

The Holothurians of the Pacific Coast of North America: H. L. CLARK.

The examination of 52 specimens, representing 11 species, from Pacific Grove, California, has thrown considerable light on the holothurians of the Pacific Coast. The occurrence of three species (*Synapta inhærens, Cucumaria calcigera, Psolus squamatus*) which also occur on the Atlantic Coast would seem to indicate that these species either are now, or have been, circumpolar forms with southward prolongations of their range on the east and west sides of the continent. The most interesting feature of the collection is the occurrence of three new species, all of which show some peculiarity in the manner of caring for the young. A small, black *Cucumaria* broods its eggs and young, while a small, red *Thyone* is viviparous, the young being found in the body cavity of the mother, as in *Synapta vivipara*. The most remarkable species, however, is the representative of a new genus, *Thyonepsolus*, which is perfectly intermediate in character between *Thyone* and *Psolus*, having the ventral surface flattened to a creeping sole covered by a thin skin, while the dorsal surface is convex and soft. On the sole the feet are in three longitudinal rows, while dorsally they are numerous and irregularly scattered. The young are carried on the back of the mother, partially imbedded in the thick, soft skin.

Structure of Clinostomum (Preliminary notice): HENRY L. OSBORN.

The finding of *Clinostomum* at Neebish, Chippewa Co., Michigan, in August, 1900,

encysted in the black bass and yellow perch, and adult in the mouth and throat of the great blue heron, gave me an opportunity to examine this form. It appears to be specifically identical with the one described by MacCallum in the *Journal of Morphology* (vol. xv, p. 697, 1899), as *C. heterostomum*, and by Braun (*Zool. Jhrb. abt. f. System*, 14, p. 1, 1900), as *C. marginatum*. There are, however, a number of points in which my material differs from the account given by MacCallum. The cuticle is armed with spines, they are very numerous, acutely tapering, run obliquely backward and are located wholly within the cuticle, barely projecting beyond its outer boundary in a few places. There is a single genital opening leading into a common chamber into which the uterus opens from in front and the cirrhus sack from behind. A pharynx as described by MacCallum is wanting. The oral sucker, as surmised by Braun, is directly followed by a characteristic œsophagus, lined with cuticle and supplied with usual longitudinal and circular muscle fibers—and surrounded by glandular cells, apparently forming the customary œsophageal gland. Circular muscle fibers are demonstrated in the intestines as well as longitudinal ones in iron hæmatoxalin stained sections. The oviduct opens into the uterus near its anterior end and not posteriorly as indicated by MacCallum. Glandular cells abound in the area directly in front of the ventral sucker, but ducts from them to the oral disk, as described by Braun, have not as yet been recognized in my material.

Note on the Marginal Sense Organs of Cotylogaster occidentalis: W. S. NICKERSON. (Paper accompanied by demonstrations.)

Members of the Trematode family Aspidobothridæ, with but one known exception (*Stichocotyle*), have a series of organs in the margin of the large multilocular sucker which have been generally regarded as sensory structures. These organs in *C. occidentalis* appear to be both sensory and glandular in function. Each is made up of a bulb-shaped body measuring about $38 \times 27\ \mu$, which communicates with the exterior by means of a narrow tortuous duct whose outer portion is lined by cuticula continuous with that covering the body. The duct arises from the distal end of the bulb, making first a sharp bend downward beside the bulb for about one-half the length of the latter, then making a second sharp turn toward the surface, where it opens directly over the bulb. The appearance of the contents of the bulb varies from finely granular to coarsely vesicular, corresponding probably with different phases of activity of the glandular protoplasm. Nuclei (except those of nerve cells) are not distinguishable in the bulb. The duct is capable of eversion so that the interior of the bulb may be protruded through the opening. A bundle of delicate nerve fibers enters the bulb at its basal end. The chief interest in the organ centers, however, in a cluster of bipolar cells lying upon the side of the bulb toward which the duct turns. These are undoubtedly sensory cells, and their peripheral processes are probably distributed upon the walls of the duct, although the exact place and method of their termination could not be made out in the specimens studied. The presence of the bipolar sensory cells establishes the sensory character of the organs which hitherto has been a matter of conjecture.

The Changes in the Facial Cartilaginous Skeleton of the Flatfishes, Pseudopleuronectes Americanus (a dextral fish) and Bothus maculatus (sinistral): S. R. WILLIAMS.

In specimens of *P. americanus* about $3\frac{1}{2}$ mm. long whose eyes are still perfectly normal in position the two supra-orbital

bars are present as in other fishes, extending from the ec-ethmoid cartilages to the otic capsules. The first indication of the coming transformation is the thinning out and disappearance of the left supra-orbital in its middle region just above the eye. Sections give evidence of the pressure exerted, since the eyeball is indented where it touches the supra-orbital. For a short time there are two regions of degeneration, one progressing toward the ec-ethmoid and the other toward the otic capsule. By the time the supra-orbital bar is resorbed the fish is at least 5 mm. long. The left eye begins to pass around to the right side of the animal through the gap prepared for it. This part of the process is comparatively rapid. After the eye shows evidence of elevation it may take the fish three or four days to assume the adult position. Nishikawa, a Japanese observer, described the passage of the eye in 24 hours in one case. Fishes of 15 mm. in length are all transformed and many take the adult position at the length of 9 mm. The twisting from left to right is greatest in the plane of the eyes, being about 120°. The brain case shows little asymmetry. The left nasal pit is raised about 30° and the anterior part of the ethmoid not much more. The mass of the ethmoid is twisted so that the left ec-ethmoid points directly up and the right down—90° from their first position. The dorsal fin, after the passage of the eye, extends forward as far as the middle of the eye.

Bothus, the sand dab, lies on its right side, whereas *P. americanus* lies on its left. But by merely transposing the terms, using *right* supra-orbital instead of left, the description just given for *P. americanus* will hold in general for *Bothus*. The dorsal fin extends to the nose ultimately in this species. The sand dab is more symmetrical than is *P. americanus*. This is correlated with its greater free-swimming habit. The flounder and the sole cling most closely to the bottom and are the most distorted.

CHAS. B. DAVENPORT,
Secretary.

ANNUAL MEETING OF THE NEW YORK ACADEMY OF SCIENCES.

THE Annual Meeting of the New York Academy of Sciences was held at 12 West 31st Street on Monday, February 25th, under the presidency of Professor Robert S. Woodward, of Columbia University. The meeting opened with the annual reports of the officers for the year just closed. The Corresponding Secretary reported that the Academy had on its list 41 Honorary Members and 206 Corresponding Members, and that five members had been lost by death during the past year. The report of the Recording Secretary was as follows:

During the last Academy year the business of the Academy has progressed in the customary paths. The several sections have held their usual meetings, with ordinarily the same attendance as in former years. The Council has held the meetings prescribed by the by-laws, and has accomplished several important objects. On the whole, however, the year can not be called a year of progress. The accomplishments of the year leading to increased efficiency in the Academy work are first, the establishment of a series of publication rules that will make the future work of the Editor, and the cost of publication much less than formerly; secondly, the vote to establish a budget for the next fiscal year, within the limits of which each officer will be required to work; thirdly, the hiring of the rooms of the Chemists' Club for the meetings of the next year, at a greatly reduced rental, with accommodations equal to those which

we now enjoy; and finally, a vote to send the *Annals* and *Memoirs* only to those members of the Academy signifying their desire to receive them. The publications of the Academy have been unfortunately delayed during the last year, owing to no fault of the Editor, but the current volume will be very shortly completed and issued. Owing to the expense of the current volume the amount of publication possible by the Academy during the next year will be seriously reduced, unless a publication fund can be established.

The report of the Treasurer showed the following receipts and expenditures for the year:

RECEIPTS.

Balance as per last report.		$2,239.11
Mortgage paid off, a/c Permanent Fund.	$1,202.75	
Mortgage paid off, a/c Audubon Fund.	1,797.25	3,000.00
Income, Permanent Fund.......	426.38	
Income, Audubon Fund........	99.04	
Income, Publication Fund......	90.00	615.42
Life Membership Fees..........		200.00
Initiation Fees.................		75.00
Annual Dues, 1897............	$ 10.00	
1898............	30.00	
1899............	170.00	
1900............	2,395.00	
1901............	50.00	2,655.00
		$8,784.53

DISBURSEMENTS.

Cost of Publications, $2,499.72.. Less Sales...... 30.06..	$2,469.66	
Cost of Publication (paid by Audubon Fund)..............	$309.72	
Rent of Rooms	510.00	
Seventh Annual Reception......	329.68	
Dues to Scientific Alliance......	32.58	
Lectures	20.00	
Expenses of Recording Secretary.	291.44	
Expenses of Librarian..........	363.95	
Expenses of Treasurer..........	41.93	
General Expenses.............	78.37	4,447.33
Balance on hand.		$4,337.20

The Librarian then presented the following report:

The work of the library during the past year has been mainly directed toward keeping the accessions catalogued and in order. This, it is believed, has been successfully carried out. The current numbers of the more prominent periodicals are placed upon accessible shelves and upon the completion of any volume, are arranged permanently with their respective sets. In this connection it is desirable to call attention to the crying need of binding many of the accessions of late years. Hundreds of volumes are stored in their pamphlet form and much injury and loss is the result. During the last year the Librarian was able to have some sixty volumes bound, but financial stringency has prevented any considerable work in this direction.

By arrangement with the authorities of the New York Botanical Garden, the bulk of the botanical portion of the library, which since the removal to Schermerhorn hall at Columbia University, had been stored in boxes, has now been deposited in the Library of the Garden at Bronx Park, and is thus more available than heretofore to general reference.

The Librarian takes pleasure in reporting a gift to the Academy from Professor D. S. Martin of about a hundred volumes of miscellaneous scientific interest.

The statistics of the Library are at this date approximately as follows:

Volumes (bound and unbound) at Columbia University	9,000
Pamphlets, at Columbia University..........	2,000
Volumes and pamphlets, at Botanical Garden.	350

Thanks to the activity of Messrs. Van Ingen and White, assisted by Mr. Graham, the files of the Academy's publications have been brought from a state of chaos to one of order, the exchange list has been revised, and the business of correspondence and exchanges is now carried on with promptness and regularity.

The Librarian takes this opportunity to call the attention of the Academy to the

absolute necessity of considering the disposition of the library in the immediate future. We have practically reached the limit of accommodations in the library room, and the department of exchanges is housed in the Gallery of the Museum of Fossil Plants and Vertebrates, in Schermerhorn Hall of Columbia University, solely by courtesy of the Department of Geology, and it has already exceeded the space which that department can conveniently spare. Radical measures must be adopted in the near future or the library must close its doors.

Following the reports of officers was the election of the honorary members listed below:

Charles Vernon Boys, 66 Victoria St., S. W., London, England.

Emil Fischer, Professor of Chemistry, University of Berlin, Germany.

William Ramsay, Professor of Chemistry, University College, London, England.

James Geikie, Professor of Geology, University of Edinburgh, Scotland.

The Academy also voted to elect the following resident members to be fellows:

Dr. Henry E. Crampton, Dr. J. G. Curtis, Dr. C. A. Herter, Professor Graham Lusk, Professor Charles Lane Poor, Mr. C. A. Post, Dr. E. L. Thorndike, Dr. R. S. Woodworth. "Fellows are limited to one hundred in number, and are chosen from among the resident members in virtue of scientific attainments or services."

Tellers were then appointed, and the officers for the ensuing year were elected by ballot as follows:

President, Robert S. Woodward.

1st Vice-President, Nathaniel L. Britton.

2d Vice-President, J. McKeen Cattell.

Corresponding Secretary, Harold Jacoby.

Recording Secretary, Richard E. Dodge.

Treasurer, Charles F. Cox.

Librarian, Livingston Farrand.

Councilors, Franz Boas, Charles H. Judd, Charles A. Doremus, M. I. Pupin, Frederic S. Lee, L. M. Underwood.

Curators, Harrison G. Dyar, George F. Kunz, Alexis A. Julien, Louis H. Laudy, E. G. Love.

Finance Committee, John H. Hinton, C. A. Post, Cornelius Van Brunt.

Following this routine business President Woodward delivered his annual address, entitled 'Observation and Experiment,' which will shortly be printed in this JOURNAL. After a vote of thanks to the President for his address, proposed by ex-President Henry F. Osborn, the meeting adjourned.

RICHARD E. DODGE,
Recording Secretary.

RECENT PROGRESS IN GEODESY.*

So much has been published during the past year in regard to recent events in the world of geodesy that there is apparently little to be said upon this occasion. But a bird's-eye or general view of a subject has its own special interest and value even to those who are familiar with the details.

It is not necessary to review the recent progress in geodesy in foreign countries, since such a review was presented in January before the Society in the form of a report upon the International Geodetic Association Conference of 1900, by Mr. Isaac Winston, the delegate on the part of the United States to that conference, and this report is in print.†

The principal geodetic enterprise now on foot in the United States is the measurement of a great arc along the 98th meridian from the Rio Grande to the Canadian border. Work upon this arc was commenced in 1896. The present state of the undertaking is that the reconnaissance is complete from northern Nebraska to the Rio Grande; that the triangulation, that is, the measurement of the horizontal and vertical angles, is complete from latitude $42\frac{1}{2}°$ in northern

* Read before the Philosophical Society of Washington, February 16, 1901.

† See SCIENCE, January 25, 1901, pp. 129–133. A more complete report upon the conference is published in *Revue générale des sciences*, Nov. 15, 1900, pp. 1175–1183; Nov. 30, 1900, pp. 1224–1233.

Nebraska to latitude $38\frac{1}{2}°$ in southern Kansas, a distance of about 300 miles along the meridian. Nine bases have been measured along this arc in addition to the Salina Base on the 39th parallel arc, which serves also to control the lengths on a portion of the 98th meridian arc. But four more bases are necessary for this arc, one at the Rio Grande and three in the Dakotas.

During the year 1900 two triangulation parties were in operation, one working northward in Nebraska and the other southward in Kansas. A base party of ten officers and men, which arrived on the working ground on July 16, 1900, in Nebraska, had by January 23, 1901, standardized the base apparatus twice, at the beginning and end of the season, and had measured the nine primary bases referred to above. The probable error of each base is less than one part in a million. If this feat of measuring nine bases as well as standardizing the apparatus in but little more than six months, while holding the accuracy up to the best standards of the past, is considered with reference to the moderate size of the party and the time which has been required for former primary base measurements, it will be seen that there has been no lack of progressiveness along this line.

One of the events of the year has been the connection of the gravity measures in the United States with those in Europe by swinging a set of the half-second pendulums, which serve to determine the relative values of gravity, at the base station at Washington and at the European stations at London, Paris and Potsdam, at which the more important European absolute measures have been made. The result of this expedition is to import, at a very small cost in time and money, the expensive and laborious determinations of the absolute value of gravity which have been made in Europe.

During the last two years the instrument and the methods used in precise leveling of the Coast and Geodetic Survey have been radically changed with a view to increasing both the accuracy and the rapidity of the work.* The evidence as to the accuracy of the new work is rapidly accumulating and so far fully justifies the changes made. The lines of leveling are being rapidly extended, a total of 1750 miles having been run during the last two years.

The most marked progress, however, in the matter of leveling has been the adjustment of the level net covering the eastern half of the United States. More than 13,000 miles of precise leveling had been run by various organizations in the United States. But until within a year the results had not been correlated. To obtain the results it was necessary to search through scores of volumes, and even when this had been done it was found that the results had been published as if each line or group of lines was entirely independent of the others, whereas in fact the connections existed for treating the whole as a single net upon one basis. The adjustment of this net has now been made. The elevations and descriptions of the four thousand permanent bench marks connected with the net, and the principal items of information in regard to each of the lines, have been published in a single volume.†

During the year the report upon the transcontinental triangulation, which marks an epoch in the history of geodesy in the United States, has been published.‡ The computation of the eastern oblique arc, extending from Maine to Louisiana has been

* See Proceedings of the American Society of Civil Engineers, November, 1900, pp. 1113–1161.

† See Appendix 8 of the Coast and Geodetic Survey Report for 1898–99, pp. 347–886.

‡ The Transcontinental Triangulation, Special Publication No 4, of the Coast and Geodetic Survey, Washington, 1900, 4to, 871 pages.

also completed * and the report will soon be ready for the printer. The relations between the measures of the earth made in the United States and the previously accepted values for the earth's size are shown in the table given below.

The last two determinations shown in the table are of light weight in comparison with the preceding three.

A study of these values will show that the modern observations in the United States indicate that the true value of the equatorial radius lies between the Clarke and Bessel values, but nearer the Clarke value, and for the polar semi-axis is a little greater than the Clarke value.

	Equatorial radius, a, in meters.	Polar semi-axis b, in meters.	Compression $(a-b)/a$.
Bessel spheroid of 1841	6,377,397	6,356,079	1/299.2
Clarke spheroid of 1866	6,378,206	6,356,584	1/295.0
Harkness, 1891. From 'The Solar Parallax and Related Constants,' Washington, 1891, p. 138. From a variety of sources	6,377,972	6,356,727	1/300.2
The spheroid determined by the 39th parallel triangulation and the Lake Survey arc of the meridian	6,377,912	6,356,309	1/295.2
The spheroid determined by the 39th parallel triangulation and Peruvian arc	6,378,027	6,356,819	1/300.7
Eastern oblique arc of the United States	6,378,157	6,357,210	1/304.5
Nantucket and Pamlico-Chesapeake arcs of meridian and Peruvian arc of meridian	6,378,054	6,357,175	1/305.5
Lake Erie arc of parallel and Peruvian arc of meridian	6,379,822	6,357,716	1/288.6

Having in mind the large number of astronomical stations attached to, and the large area covered by, the arcs already utilized in the United States, as indicated above, it is reasonably safe to predict that if the United States is eventually completely covered by triangulation and astronomical stations are liberally supplied everywhere, and the mean figure deduced from these observations alone, regardless of those made in other countries, neither the equatorial radius nor the polar semi-axis so computed will differ from the Clarke values of 1866 by as much as 500 meters, and it is about an even chance that either value will not differ from the corresponding Clarke value by more than 170 meters, this being about the height of the Washington monument. In other words, there is little likelihood that the Clarke spheroid of 1866 now used as the standard in this country differs from the spheroid which will most nearly fit this country alone by more than one part in 12,000, and there is an even chance that it does not differ from it by more than one part in 36,000.

It is reasonably safe to make the same prediction in regard to the earth spheroid, or the spheroid which will most nearly fit all the measures which may hereafter be made in all countries, as has been made above for the spheroid which will most nearly fit the United States.

JOHN FILLMORE HAYFORD.

THE SAN JOSE SCALE IN JAPAN.

THE insidious invasion of the eastern United States by the San Jose scale (*Aspidiotus perniciosus*)—the name gives undeserved notoriety to the California city—has come to be so formidable that the pest is now recognized as one of the most seriously threatening dangers to American

fruits. In thirty-five or more States and Territories, and in Canada, the insect is recognized as a scourge. The invasion has been met by the active antagonism of economic entomologists, State Legislatures and fruit growers. A dozen or more States have passed laws providing for the inspection of nursery stock and fruits brought into the State, and for the destruction of stock found to be infested by the scale. The life history of the insect has been carefully studied, the effects of new climatic and topographic environment noted, and new remedies devised and tested. The attention this tiny degenerate insect has received puts it in that notorious list of insect scourges of the first class which includes the chinch bug, the Hessian fly, the Colorado potato beetle, the codlin moth and other familiar pests.

It is recognized more clearly to-day than ever before, how all important in keeping insect pests in check are their natural enemies, predaceous and parasitic, and of how much less avail in most instances are the artificial defenses and offenses which man has devised. The natural remedies are immensely more effective than the artificial remedies. Indeed so extreme a view of the whole matter of insect-fighting is held by some entomologists that they openly commend a 'laissez-faire' policy in economic entomology except as regards purely localized efforts. My own feeling is that of much sympathy with this reaction against the multiplied, expensive and oftentimes conspicuously ineffective artificial panaceas. On the other hand, where the economic entomologist bases his war strategy on a thorough study of the life history and ecology of the particular insect enemy engaged with, and where he seeks primarily to discover natural aids for his attacks, where he thinks first of encouraging and strengthening the natural defenses of the attacked and of reenforcing the natural barriers to the spread and increase of the attacking pest, he is, it seems to me, on the way to do the best work for the suffering orchard or grain field.

One of the promising lines of work of this kind is the search for and the importation and propagation of the natural enemies (usually predaceous or parasitic insects) of introduced foreign pests. The too successful naturalization of these foreigners is in most instances due, presumably, to the fact that they come to us unaccompanied by their natural native enemies. Free from the principal check to their increase, they multiply and spread with alarming rapidity (providing the conditions of climate and topography permit), giving us a momentary glimpse of life uncontrolled by the balance wheel of one phase of the struggle for existence. It is quite true that much that is ill-considered and imaginative has been spoken and written regarding the success of the importation of parasites. And the expectations of the uninformed, or rather of the falsely informed, are hardly likely to be met soon. But there is an encouraging residuum of fact left after the froth and bubble have been blown from the California stories. The *Vedalia* has really eaten up about all the cottony cushion scale (*Icerya*); and some other imported lady-birds are really eating up a good many other scales. I believe that it is at least worth while to see if there is any hope of getting some active and competent lady-bird beetle to look after the San Jose scale.

But to search for the native enemies of the San Jose scale it is necessary to know the nativity of the scale itself. And this is something as yet undetermined (unless, it has been determined by the investigation about to be written of). Without canvassing in detail opposing claims for the honor, it is sufficient to say that Japan and California are the two leading claimants in the

matter; each claiming that the other is the native home of the pest. With this generous rivalry in mind, and with the further thought of the desirability of finding an effective natural enemy of the San Jose scale, Mr. Shinkai I. Kuwana, Assistant in Entomology at Stanford University, spent all last summer in Japan collecting and studying in the field the Japanese scale insects (the first attempt at a systematic investigation of the Japanese Coccidæ), paying special attention to the San Jose scale. Mr. Kuwana's collections are large, and his notes many, and interesting. His familiarity with the language, the customs and the geography of Japan gave him special advantages in the work.* He visited all the large islands of the empire, penetrating into the interior among the mountains, as well as examining the coast line orchards. He was greatly aided by Japanese naturalists and fruit growers, and altogether was able to make an extended reconnaissance.

As a result of this exploration it is certain that the San Jose scale is widely and commonly distributed over the whole empire of Japan (excepting on the island Shikoku), though in but few places is it a serious pest. It is found on the following hosts: Pear, apple, plum, peach, Japanese quince, currant, willow (*Salix gracilistyla*), and *Paeonia montana*. It is found especially common in young orchards where its chief injuries are done. It is present in certain of the very old interior orchards, where it has been known, under the name Ki-Abura, for more than thirty years. It is attacked by several enemies, Mr. Kuwana personally finding one chalcid, three lady-bird beetles and one moth, the larva of which feeds on the scale. Of these enemies the chalcid fly and one of the lady-bird beetles are everywhere common, and are effective checks to the increase of the scale. It is probable that the comparatively little injury produced by the scale in Japan, widespread as it is, is due to the presence of these natural enemies. The artificial remedies used in Japan against the scale include 'soap water,' solution of caustic soda, and kerosene. The soda solution (one pound caustic soda to 10 gallons of water) is applied with cloths and the trees then washed with pure water. The other insecticides are applied with a Japanese paint brush. After a rain the fruit growers go into the orchards with ropes or cloths and rub off the scales while wet.

Variation among individuals of the scale is apparent but not considerable. The scales are uniformly dark, either black or dark brown. The white secretion covering the exuviæ of the males is comparatively scant, in some cases almost wanting. The chitinous processes on the posterior margin of the abdomen of the female vary somewhat, but the relative size and arrangement remain fairly constant. There may be as much difference, indeed, between the processes of the two sides (lateral halves) of this margin as between the processes of two individuals.

Mr. Kuwana's observations point strongly to the Japanese nativity of the scale, or at least to its inhabitancy of Japan prior to its brilliant career in North America. It must be noted, however, that the scale was not found strictly 'wild' in Japan; that is, it was not found on any wild (uncultivated) tree in its natural habitat. The willow trees found infested with scales were in the ground of the Government Forestry Station at Nishigawara. The scale was, indeed, found on mountain (or wild) pear trees, but these trees were in or near an old apple orchard.

VERNON L. KELLOGG.
STANFORD UNIVERSITY, CAL.

* Mr. Kuwana's own detailed report of his investigation can not be ready for publication for several months.

SCIENTIFIC BOOKS.

Studies in Fossil Botany. By DUNKINFIELD HENRY SCOTT, Ph.D., etc. London, Adam and Charles Black, The Macmillan Company. 1900. Pp. 533. Illustrated. Price, $2.75.

The gathering force represented in the paleontological researches of the last quarter of a century is now finding expression in publications which not only summarize the results reached by individual investigators, but which coordinate them and thereby give them a positive value as contributions to our knowledge of the character and succession of plant life in past times. The closing years of the nineteenth century witnessed the issue of three important works by Potonié, Seward and Zeiller. The initial work of the twentieth century by Scott may well take rank with them, and it offers the most hopeful indication of what we may reasonably expect from the paleobotanical work of the future. All these works have the common characteristic that they approach the subject from the standpoint of modern phylogeny, and we may, no doubt, safely conclude that they represent the completion of that 'harmony between the botany of extinct and existing forms' which botanists have always regarded as most essential, but the realization of which has been long deferred. They place the whole subject of paleobotanical research upon an entirely new basis, and this branch of botanical inquiry is now emerging from a condition which may well be compared with the transition from the Old to the New School of Botany in 1860.

In presenting his 'Studies in Fossil Botany,' Dr. Scott does not wish us to infer that he is attempting to produce a manual or even a textbook; but his contribution is founded upon a course of lectures delivered in 1896, which he has now brought down to date, and the title clearly indicates that he avoids the particular field already occupied by Potonié, Seward and Zeiller, whose works follow parallel though dissimilar lines of treatment. The purpose of the author is expressed in the statement that the work is designed to present results which appear to be of fundamental importance, and he therefore confines his attention to a few of the leading groups of plants within which the greatest advances of recent years have been made, and where most tangible results have been secured. Other publications give greater detail respecting species, taxonomy and geological relations, but the present work acquires special importance and value because of the close insight into relationship disclosed by a detailed study of comparatively few types on the bases of ample material and remarkably well-preserved specimens. His presentation is a statement of facts rather than an exposition of views. We may not only sympathize with him in the hope that the paleontological record will no longer be ignored by students of the evolution of plants, but also express the conviction that in the future botanists will *not* ignore such evidence, simply because they can not afford to do so.

The material used is primarily that which Williamson gathered during his lifetime, together with such additional material as has come to the hands of Dr. Scott and others in more recent years. The author adopts Solms-Laubach's principle of 'the completion of the natural system' as his point of departure. He therefore discards all problematical forms and confines his attention solely to the relatively few types which contribute well-ascertained data. All discussions center in phylogeny, and the work stands as one of the best expositions of the importance which attaches to the study of fossil plants as a necessary means of completing such data.

After a brief discussion of the relations of plants in geological time and their methods of preservation, the author immediately proceeds to a consideration of the Pteridophyta and the lower Seed Plants, and in a very lucid and convincing manner places before the reader the essential facts in the structure, reproduction and relationships of those plants in which the paleontological progress of the past twenty years has centered. In the main, the illustrations are taken from Williamson's works, and a very striking and pleasing feature appears in a skilfully executed restoration of *Lyginodendron Oldhamianum* which is introduced as a frontispiece.

In the present condition of our knowledge, a classification of the Calamarieæ is difficult in

consequence of the fragmentary character of the material. For this purpose the fructification which, as also the stem, had a complexity of structure unknown in modern representatives of the Equisetineæ, affords the most satisfactory basis, and the system proposed by Weiss, in which he makes use of such external characters as scars, is shown to be of no value except for geological purposes. In *Calamostachys Casheana* the axis of the cone shows a secondary growth in the vascular system and thus gives a final negative to the view so strongly advocated by Brongniart, that secondary growth in the wood is a certain characteristic of the phanerogams. The Calamarieæ show no transitional forms with the Coniferæ, and can not be regared as their progenitors. In fact, our knowledge of these plants is at present so inadequate, that we can not regard them as anything more than a highly organized family of the vascular cryptogams closely allied to the Equisetineæ. But the question still arises if they show any affinities with any of the seed plants? If such affinity exists, it would probably appear in the direction of the Coniferæ or possibly of the Gnetaceæ. The anatomy of the stem certainly approaches the former, while the structure and simple form of the leaf are not without significance. It is also true that the relative positions of the sporangiophore and bract in *Paleostachys* have been compared with those of the ovuliferous and carpellary scales of the Abietineæ, but it is altogether probable that these examples are nothing more than interesting parallels in development which have no force in establishing relationships, and these latter must be sought in other directions, especially as there are no transitional forms connecting the two groups.

The Sphenophylleæ represent a group of the greatest phylogenetic interest, inasmuch as they occupy a position of which there is no representative among existing species. The genus *Sphenophyllum* constitutes a perfectly distinct group of which all the parts are well known in one species or another, and there is no longer room for the idea that these plants represent the foliage of a Calamite. Heterospory may have been present, but so far there is no direct evidence in support of such a view.

The remarkable cones known under the name of *Cheirostrobus pettycurensis* have as yet not been found in connection with other parts of the plant, so that it is impossible to determine the exact nature of the organism to which they belonged. So far as known, however, they were homosporous, but the material now available does not admit of final conclusions in this respect. It is nevertheless certain that these cones were of a remarkably complicated type, and while in the character of the sporangiophores, and in the insertion and structure of the sporangia they exactly agree with the Calamarian type, the anatomy of the axis shows them to approach the Lepidodendroid lycopods, whence we may conclude that they represent a synthetic type combining the characters of different groups of plants.

From these facts Dr. Scott draws the inference that the Sphenophyllaleæ were highly modified representatives of an ancient stock from which both the lycopods and the Equiseti have diverged, but our knowledge of these phyla rests at present entirely upon the evidence of fossil plants.

In *Lepidodendron*, the well-defined presence of ligules serves to indicate a connection with *Selaginella* rather than with *Lycopodium*, a view which would seem to gain additional strength from the observed heterospory of *Lepidostrobus Veltheimianus*. Another feature of exceptional interest is the fact that in some of the cones of Paleozoic lycopods, the origin of which has been fully traced, an integument is formed about the macrosporangium in such a way as to produce a seed like body which eventually becomes detached, as exhibited in the well-known *Cardiocarpon anomalum* of Williamson; and this development is repeated in *Lepidostrobus*, where the microsporangia are similarly invested by an integument. In this we obtain the first definite indication of those transitional forms which serve to connect the Cryptogams with the higher seed plants.

The earlier views of Brongniart, which placed the *Sigillarias* among the Gymnosperms, are shown to rest primarily upon the fact that the first described *Lepidodendron* (*L. Harcourtii*) is devoid of secondary wood growth, and emphasis is placed upon the now well-known

fact that the Sigillarieæ have not even a remote connection with those plants.

Stigmaria is held to represent a rhizophore, of which the stigmarian appendages would therefore be the roots. From this point of view these remains must be regarded as representing organs comparable with the rhizophores and roots of existing Selaginellas.

Dating from Silurian time, the ferns gained special prominence in the Carboniferous, where it is even yet difficult to separate the true ferns from fern-like plants. The author nevertheless adopts the conclusions of Bower and Campbell respecting the relative antiquity of the Eusporangiatæ and Leptosporangiatæ as amply justified by paleontological evidence, which also gives support to the classification of ferns by Bower on the basis of the development of the sorus and the output of the spores. In this, the division into Eusporangiate and Leptosporangiate is subordinated to the development of the sporangia with reference to time and place.

One of the most remarkable and significant results of paleontological research in recent years has been the recognition of the Cycadofilices as established by Potonié, thus forming a connecting link between the ferns and the Gymnosperms through the Cycads. Dr. Scott rightly places special stress upon an elucidation of the characters of this important group and shows:

1. That hitherto supposed forms of *Alethopteris*, *Sphenopteris* and *Neuropteris* types really represent the foliage of Cycadofilices.

2. The anatomical characters of the stem are in close agreement with those of the Cycadaceæ.

3. While the exact character of the fructification is not known with certainty, that which in all probability belongs to those plants is widely different from that of the ferns and approximates to that of the Cycads.

Poroxylon is shown to be a transitional form between the Cycadofilices and Cordaites through *Lyginodendron*. With respect to the Cordaiteæ to which he deservedly devotes a large measure of space, he fittingly summarizes prevalent views respecting this most important group when he says that "Further investigation will doubtless modify greatly our conception of the Cordaiteæ, and display a much greater variety among the members of this family then we are at present prepared for. But whatever the future may have in store for us in this respect, there can be no doubt that the revelation of the existence of this fourth family of Gymnosperms was a discovery of the first magnitude, which reflects the greatest credit upon the investigators to whom it was due, and profoundly modifies our whole conception of an important sub-kingdom of plants."

Among the Mesozoic Cycadales, the genus *Bennettites* gains special prominence and importance, not only because of the great perfection with which important structures are preserved, but because of the character of the fructification and the relatively high development attained by these plants. The stem structure agrees closely with that of the Cycadaceæ, though representing a more primitive type. On the other hand, the fructifications of the two groups are totally different, and the greater complexity attained in the Bennettiteæ points to a considerably higher degree of development. Thus in *B. Gibsonianus*, the seeds, many of which are to be found in a remarkable state of preservation, are dicotyledonous and exalbuminous, while the whole character of the fruit approximates to that of an Angiosperm. Here again we observe a repetition of that parallelism in development between various branches of the phylogenetic tree which was so well exhibited in *Cardiocarpus* and *Lepidostrobus*, and which goes far to sustain the idea so frequently suggested throughout the plant world, that in the general progress of development, the various branches are all extending forward in the same direction, whence arises a parallelism which indicates approximation to, without actual connection with, other yet higher phases of development; or, in other words, that deviation of a branch from the main line of descent involves certain inherent deficiences which, while permitting development in the same general direction, impose a definite limitation of such a nature that the phylum is incapable of further variation, and hence can not extend beyond a limit which is always much inferior to that attained by the main line.

The work throughout affords one of the best evidences among recent contributions of the

primary importance of anatomical characters as the basis of true relationship, and this book will do much toward dissipating the older and altogether fallacious idea that a classification of fossil plants based upon external characters alone is possessed of permanent value. While the external forms of plants or their parts may possess a certain value for taxonomic purposes, such characters are in all probability least reliable in the case of fossils where they depend so largely upon the modifying influence of conditions under which the plant has been preserved. They are therefore oftentimes most misleading, and although we may admit their general value as a provisional means of classifying remains which cannot be otherwise distinguished, they possess no scientific merit and should be abandoned as fast as more accurate data become available.

That this book will do much to stimulate a more active interest in this important line of research we cannot doubt, but its mission will be well accomplished if it does no more than to finally convince botanists of their real dependence upon data derived from a study of the extinct forms of plant life.

D. P. PENHALLOW.

MCGILL UNIVERSITY,
Feb. 6, 1901.

A Contribution to the Study of the Insect Fauna of Human Excrement. By L. O. HOWARD. Proc. Washington Academy of Sciences, Vol. II., pp. 541–604. 2 pls.

A brief summary of the results obtained by Dr. Howard in his study of the insects affecting human excrement was given in the *Popular Science Monthly*, January, 1901. We have now before us the detailed work, in which the insects concerned are fully discussed and in many cases figured.

No resident of this country is likely to forget the deplorable outbreaks of typhoid fever which occurred in the military camps at the time of the war with Spain. It appears that every regiment in the United States service in 1898 developed typhoid, while more than 80 per cent. of the deaths in camp were due to this disease. This condition of affairs naturally aroused a great deal of popular anxiety and indignation, while medical men bestirred themselves to discover the exact causes of the spread of the fever. As a result, it came to be generally believed that flies had a great deal to do with the spread of typhoid bacilli, and one of the most prominent medical investigators concluded that 'flies undoubtedly served as carriers of the infection.'

Admitting, then, the agency of flies in the spread of typhoid fever and other ills, the question naturally arose, 'What flies?' This question the medical men did not pretend to answer, and the way was clearly open for an entomologist to supply the desired information. Dr. Howard, who loses no opportunity to make the Division of Entomology serviceable to the public, at once began an investigation which has now resulted in the publication of exact and minute details to take the place of supposition and vague surmise. Not only were the insects frequenting human excrement carefully watched and recorded, but feces were collected in great numbers, and the species breeding in them ascertained. As had been anticipated, flies were found in plenty; in fact, no less than 77 different species were obtained, of which 36 were actually found breeding in the feces. In addition to this, 23,087 flies were caught in kitchens and pantries in different parts of the country, in order to see how many of the kinds visiting or breeding in human excrement also visited places where food was kept, and were likely to crawl over the food. It appears that the flies most commonly found breeding in human excrement are not those which frequently enter dwellings, but there are several species which are likely to pass directly from the excrement to places where food is kept, and so become a dangerous source of infection. This is true of the common house fly (*Musca domestica*), the vinegar fly (*Drosophila ampelophila*), the stable fly (*Muscina stabulans*) and a number of others.

The practical conclusions reached by Dr. Howard should become known to all municipal authorities. It is shown that human excrement is much more dangerous to the public health than dead animals or other refuse. Every care should be taken to provide for its removal from those places where flies can gain access to it, and those depositing it in by-ways and vacant

lots should be severely punished. It seems to the present writer that the excrement nuisance, which now appears in a new and more serious light, cannot be got rid of until city authorities see their way to provide places of public convenience in every ward, so that no one need resort to either the alleys or the saloons to obey the dictates of nature. Dr. Howard has, indeed, provided the municipal reformer with a new and valuable argument, which it is to be hoped he will not fail to use.

From the standpoint of scientific entomology Dr. Howard's paper is of much interest. It records for the first time the breeding habits of a large number of insects, and also adds greatly to our knowledge of their distribution. Three species of flies proved to be new to science; these have been described by Mr. Coquillett in *Entomological News*, January, 1901.

In all the work Dr. Howard was ably assisted by several members of his office force, particularly Messrs. Pratt and Coquillett. To these careful credit is given, in accordance with Dr. Howard's invariable custom. The figures are numerous and clear, 25 species being illustrated, often with the early stages. By some slip, *Drosophila ampelophila* is called '*ampelophaga*' on the plate, but the name is given correctly in the text. *Limosina albipennis* and *L. crassimana*, to judge from the figures, should belong to different genera.

SCIENTIFIC JOURNALS AND ARTICLES.

The Journal of Physical Chemistry. December. 'Reaction Velocity and Equilibrium,' by Wilder D. Bancroft; 'Differences of Potential between Metals and Non-aqueous Solutions of their Salts,' II, by Louis Kahlenberg. A formula has been deduced by Nernst for the E. M. F. of a galvanic chain of the type

$$Ag \mid AgNO_3 \text{ (concentrated)} \mid AgNO_3 \text{ (dilute)} \mid Ag$$

which shows a fair degree of agreement with the observed values when water is used as a solvent. The author has tested the formula experimentally in a number of cases in which non-aqueous solutions are used, and finds that Nernst's formula does not hold good under these circumstances; 'Solvent Action of Vapors,' by A. T. Lincoln. A study of the solvent action of the vapor of water, benzene and acetone upon salicylic and benzoic acids, and of alcohol vapor upon camphor and naphthalene.

January. 'Gas Polarization in Lead Accumulators,' by C. J. Reed; 'Two Devices for Circulating Liquids at a Constant Temperature,' by Ira H. Derby; 'On the Equilibrium of Chemical Systems,' by Paul Saurel. The translation of the more important parts of a thesis of the same title, presented to the Faculté des Sciences of Bordeaux.

The first (January) number of Volume II. of the *Transactions* of the American Mathematical Society contains the following papers: 'Invariants of Systems of Linear Differential Equations,' by E. J. Wilczynski; 'Divergent and Conditionally Convergent Series whose Product is Absolutely Convergent,' by Florian Cajori; 'Sets of Coincidence Points on the Non-Singular Cubics of a Syzygetic Sheaf,' by M. B. Porter; 'Note on Non-Quaternion Number Systems,' by W. M. Strong; 'On the Reduction of the General Abelian Integral,' by J. C. Fields; 'Ueber Flächen von Constanter Gauss'scher Krümmung,' by David Hilbert; 'Note on the Functions of the Form $f(x) \equiv \varphi(x) + a_1x^{n-1} + a_2x^{n-2} + \cdots + a_n$ which in a given Interval differ the least possible from Zero,' by H. F. Blichfeldt.

The February number of the *Bulletin* of the American Mathematical Society contains the fol-

lowing papers: 'Report of the Annual Meeting of the Society,' by the Secretary; 'On Some Birational Transformations of the Kummer Surface into Itself,' by Dr. J. I. Hutchinson; 'Theorems concerning Positive Definitions of Finite Assemblage and Infinite Assemblage,' by Mr. C. J. Keyser; 'Dini's Method of showing the Convergence of Fourier's Series and of other Allied Developments,' by Mr. Walter B. Ford; 'Shorter Notices'; 'Fehr's Application of the Vectorial Analysis of Grassmann to the Infinitesimal Geometry,' by Mr. E. B. Wilson, and 'The Annuaire du Bureau des Longitudes,' by Professor E. W. Brown; 'Notes'; 'New Publications.'

The Plant World for January comes in a new and improved garb externally and internally. The first article, by Alice Carter Cook, entitled, 'Some Filipino Botany' comprises some curious extracts from Blanco's 'Flora.' C. F. Saunders contributes 'Hints for Beginners in the Determination of Grasses,' and an excerpt from Bulletin 28, Division of Forestry, discusses 'The Threatened Destruction of the Big Trees of California.' E. M. Williams describes 'The Rosy Tricholoma' and C. L. Pollard in the supplement continues 'The Families of Flowering Plants,' treating of various families of the orders Polygonales and Centrospermæ.

The American Naturalist for February is a particularly strong number in spite of the absence of 'Editorial Comment and Reviews.' It opens with a long and critical review of 'Scharff's History of the European Fauna' by Leonhard Stejneger, Scharff's work being praised for its admirable suggestiveness and treatment of the subject, though Dr. Stejneger combats, we think successfully, his advocacy of an invasion of Europe from North America by way of Greenland. B. Arthur Bensley discusses 'The Question of an Arboreal Ancestry of the Marsupialia and the Interrelationships of the Mammalian Subclasses,' considering that in spite of all evidence presented, Huxley's theory of a genetic succession of the former representatives of the Monotremata, Marsupialia and Placentalia is still entitled to first consideration. Arnold E. Ortmann briefly reviews 'The Theories of the Origin of the Antarctic Faunas and Floras,' stating that he accepts Hooker's general idea of the former existence of land connection between the southern portions of existing continents. Oldfield Thomas writes of 'The Generic Names *Myrmecophaga* and *Didelphis*,' claiming that the former name justly belongs to the Great Ant-eater and *Didelphis virginiana* to the Virginia opossum. The species *cinereus* and *alstoni* he considers as members of the genus *Marmosa*. Finally Edwin C. Eckel presents 'The Snakes of New York; an Annotated Check List,' giving twenty-five species and subspecies, this being the first paper on the ophidian fauna of New York since Baird's 'Serpents of New York.'

Numbers 62 to 66 of the interesting *Communications from the Physical Laboratory at the University of Leiden* have been received in this country. The preceding numbers of the series are mainly in English. These numbers are in German except No. 65, which is in French. All are reprints from the *Livre jubilaire dédié à M. Prof. Lorentz.*

THE MACMILLAN COMPANY, agents of the New York University Press, will publish early in March, the first number of a scientific quarterly under the title *New York University Bulletin of the Medical Sciences*, edited, under the auspices of the New York University Medical Society, by an editorial committee consisting of B. Farquhar Curtis, M.D., Robert J. Carlisle, M.D., E. K. Dunham, M.D., John A. Mandel and William H. Park, M.D.

SOCIETIES AND ACADEMIES.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 315th meeting of the Anthropological Society was held on February 12th. Mr. Paul Brockett gave a short paper on 'Ancient Mexican Books,' and exhibited a copy of the Borgian Codex, lately reproduced through the munificence of the Duc de Loubat. With the codex was shown a Japanese book, illustrating the similarity in methods of folding. 'The Unwrapping of a Peruvian Mummy,' by W. H. Holmes and Walter Hough, proved interesting. A mummy pack from Peru was divested of its wrappings and from the swathings of cotton-bolls, leaves and cloth were taken the skeletons

of an adult and two infants. With the bodies were fabrics, pottery, gourds, a basket of two compartments containing a thorn needle, thread, red pepper and spinning apparatus. The presentation was further illustrated with plates from Reiss and Stübel's 'Necropolis of Ancon.'

W. H. Holmes presented a valuable paper on 'The Peopling of America,' in which a wide range of topics was discussed and illustrated by diagrams. It was aimed especially to bring forward the various problems involved in the new light thrown upon them by recent geological research. The biological problems were presented with the aid of a diagram outlining the history of the species and fixing the apparent position of the American people among the races of the world. Problems of chronology were elucidated by means of a diagram in which the genetic tree of the hominidæ was made to traverse the geologic time scale. Taking root in Tertiary times, the human stem is believed to have sent out four or more branches during Glacial and post-Glacial times, the latter period probably witnessing the specialization of the present American branch. The various views with respect to the geographical position of the cradle of the race were reviewed, and distribution and differentiation were discussed. Preference was given to the view that the eastern rather than the western continent was the original home of the group.

In the fourth section, the bridges and ferries by means of which America could have been occupied were passed in review, and the conclusion was reached that, so far as the present populations are concerned, they must have arrived by way of Bering Strait and that they were thus necessarily of Mongolian stock. Possible interference of the glacial ice sheet was considered, and the probabilities of pre-Glacial, inter-Glacial, and post-Glacial migration weighed.

The seventh section dealt with migration and the laws that govern movements of faunas and peoples, and the effects of movements of human groups from Asia to America by Bering Strait upon somatic and cultural conditions were carefully presented.

The eighth section included a comparative study of American culture with reference to questions of origin; and the concluding section presented the archeological and paleontological evidence with the view of determining, as far as possible, its bearing upon questions of time, people and culture. It appeared that, although many phases of the investigation are yet in the speculative stage, comparative anthropology and geology are gradually but surely bringing order out of chaos.

Major Powell, in discussing Professor Holmes's paper, urged strongly that the tendency in culture development is toward integration and not toward differentiation. He pointed out that the number of languages in America evidences a low culture status, and affirmed that a similarly low status had been observed among certain tribes of Indians, as to artifacts. These remarks were in support of Major Powell's hypothesis that the precursor of man entered America destitute of speech and arts and at a period when Alaska was a land area coincident with Asia.

Mr. McGee said, in reference to the chronology of the hominidæ, he would place the precursor well down in the Glacial period, when the change began from divergence to integration. He said that development is by that process, and instead of representing the races by a number of radiating lines, he would show the divisions of the human race by converging lines developing toward unity.

Professor O. T. Mason, whose work on these problems is well known, was unfortunately unable to be present.

WALTER HOUGH.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 334th meeting was held on Saturday evening, February 9th. H. C. Oberholser spoke on the subject of 'A Naturalist in the Catskills,' describing at some length the topography of the region, the character of the vegetation and the more prominent birds and mammals, illustrating his remarks with numerous lantern slides. The remainder of the evening was devoted to a continuation of the discussion of the question of previous land connections between Asia and North America. Theo. Gill reviewed the evidence presented by the fossil mammals and existing fishes, saying that there

had not been one, but several land connections between the continents during the past.

Vernon Bailey said that nine species and subspecies of voles inhabiting the islands, coast and barren grounds of Alaska, belong to a well-defined group in the subgenus *Microtus* not represented elsewhere in America, but largely represented in Siberia and Northern Europe, *M. aperazius* of St. Michaels, for example, being closely related to *M. arvalis* of Europe. Among the red-backed voles *Evotomys alascensis* of the barren grounds of Alaska is much more nearly related to *E. rutilus* of northern Siberia and Europe than to any other American species. As these animals were small and weak and must therefore travel and spread slowly, he concluded that they could not have crossed over an ice bridge, but that their affinities pointed to a comparatively recent and somewhat extended, in point of time, land connection.

F. A. LUCAS.

THE NEW YORK SECTION OF THE AMERICAN CHEMICAL SOCIETY.

THE monthly meeting of the New York Section of the American Chemical Society was held on February 8th at the Chemists' Club, 108 West Fifty-fifth street.

Dr. T. C. Stearns read a paper on 'The Chemistry of Materials used in Perfumery and Kindred Arts,' in which he described the methods of preparation and chemical relations of the essential odors of flowers and their synthetic imitations.

In the discussion it was suggested, and by some maintained, that the effect of the synthetic preparations was harmful to the human system, but nothing whatever in the way of proof was adduced.

Dr. C. W. Volney gave the results of his investigation of the 'Decomposition of the Chlorids of the Alkali Metals by Sulfuric Acid,' with exhibition of crystals, which he considered polysulphates, the most important being the trisulphate. Some of those present thought these salts were probably acid sulphates, with sulfuric acid of crystallization, and that even the thermal evidence was in support of this explanation.

A paper by Dr. H. T. Vulté and Harriet W. Gibson on the 'Metallic Soaps from Linseed Oil; an Investigation of their Solubilities in certain of the Hydrocarbons,' was read by Dr. Vulté. Professor Sabin said that a great many of the driers in use were made from rosin and contained no linseed soaps at all. Dr. Dudley said that he knew of no subject needing more study than the chemistry of the drying of oil, and that a great deal of time had been spent on it in his laboratory. He found that oil driers used in excess retard drying, but that gum shellac driers could be used in all proportions and drying would occur approximately in proportion to the drier used. He had also found that a lead and manganese drier could be prepared which would induce drying of linseed oil in two hours.

H. C. Sherman and J. F. Snell were represented by H. C. Sherman, who read a paper in two sections: (a) 'On the Heat of Combustion as a Factor in the Analytical Examination of Oils'; (b) 'The Heats of Combustion of some Commercial Oils.'

It was shown that in the case of a drying oil exposure to the air produced a reduction in the heat of combustion which may amount to ten per cent., whereas lard oil with the same exposure lost only one per cent. of its heat of combustion.

To ignite the oil in the bomb calorimeter it was found satisfactory to absorb it on asbestos wool, whereby the use of any special igniting substance, with its consequent introduction of a troublesome error, was entirely obviated.

DURAND WOODMAN,
Secretary.

THE WESTERN PHILOSOPHICAL ASSOCIATION.

THE Western Philosophical Association held its first annual meeting at the University of Nebraska, Lincoln, on January 1st and 2d. The program was as follows:

Greetings—Chancellor E. Benjamin Andrews, University of Nebraska.

President's Address—'The Theory of Interaction'—Frank Thilly, Professor of Philosophy, University of Missouri.

'The Dominant Conception of the Earliest Greek Philosophers'—Frederick J. E. Woodbridge, Professor of Philosophy, University of Minnesota.

Discussion led by Arthur Fairbanks, Professor of Greek, University of Iowa.

'Martineau's Heredity and Philosophy'—Rev. J. R. Brown, of Kansas City.

Discussion led by C. B. McAfee, Professor of Philosophy, Park College.

'The Psychology of Profanity'—G. T. W. Patrick, Professor of Philosophy, University of Iowa.

Discussion led by D. D. Hugh, Professor of Psychology, State Normal School, Colorado.

'The Postulates of the Psychology of Style'—J. D. Logan, Professor of Philosophy, University of South Dakota.

Discussion led by L. A. Sherman, Professor of English Literature and Dean of the College of Arts, University of Nebraska.

'Some Philosophical Problems of the Present Time'—An informal address by J. E. Creighton, Professor of Logic and Metaphysics, Cornell University, and editor of the *Philosophical Review.*

'The Primacy of Will'—Edgar L. Hinman, Adjunct Professor of Philosophy, University of Nebraska.

Discussion led by W. M. Bryant, of St. Louis.

'The Psychology of Imitation'—T. L. Bolton, Instructor in Psychology, University of Nebraska.

Discussion led by H. Heath Bawden, Instructor in Philosophy, University of Iowa.

'The Theory of Imitation in Social Psychology'—C. A. Ellwood, Assistant Professor of Sociology, University of Missouri.

Discussion led by A. Ross Hill, Professor of Philosophy, University of Nebraska.

The meeting next year will be at the University of Iowa under the presidency of the University of Iowa.

DISCUSSION AND CORRESPONDENCE.

CROCODILIAN NOMENCLATURE.

Mr. William J. Fox (Science, February 8, 1901, p. 232) in maintaining that the name *Lacerta crocodilus*, given by Linnæus, has become restricted to the Nile crocodile by its exclusive use for the latter in Hasselquist's 'Reise,' 1762, has apparently overlooked the fact that the types of *Lacerta crocodilus* are still in existence. It has been shown both by Dr. Lœnnberg and Mr. Andersson that the specimens which served Linnæus as types for his descriptions belong to the species which is commonly known as *Caiman sclerops.* As the generic name of the latter is also untenable, the species will stand in the future as *Jacaretinga crocodilus* (Linnæus), while the name of the crocodile of the Nile remains as before: *Crocodylus niloticus* Laurenti.

Leonhard Stejneger.

U. S. National Museum,
Feb. 16, 1901.

SHORTER ARTICLES.

STRATIGRAPHICAL NOTE.

In Science, N. S., Vol. XIII., No. 317, January 25, 1901, p. 135, I notice that the order in which the proposed names of the geological formations occurring in the Devonian and Silurian of Antigonish County, Nova Scotia, is given, might lead to a misapprehension of the natural succession of the strata in question. I have much pleasure in drawing attention to the following notes on the names suggested and characteristics of the five geological formations as they appear, in descending order, as follows:

Devonian.

1. The Knoydart formation. (Knoydart being the name of a settlement and brook in the vicinity of McArras brook, where this formation is well developed. The word is pronounced as if spelt Kroydiart.)

The Knoydart formation consists of red shales and sandstones, marls and tufaceous strata holding pteraspidian and cephalaspidian fishes associated with crustaceans whose affinities are close to a number of forms described from the Cornstone or Lower Old Red Sandstone of Great Britain, especially as developed in Herefordshire.

This Knoydart formation is thus referred to the 'Old Red Sandstone' or Devonian System.

Silurian.

Unconformably (?) below the Knoydart formation we find just east of the mouth of McArras Brook and along the south shore of Northumberland straits at this point, Silurian strata, holding marine organisms, which may be provisionally divided into *four* distinct formations.

2. The Stonehouse formation. This consists for the most part of dark red thin-bedded, fine-grained, shales or mudstones with a conspicuous and abundant lamellibranchiate fauna,

of which *Grammysia Acadica*, Billings, is a well-known species, together with a number of interstratified, more or less, calcareous band-holding branchiopoda, gastropoda, trilobites and ostracods in abundance.

3. THE MOYDART FORMATION (pronounced Mōdiart). This consists for the most part of heavy-bedded, light greenish gray and rusty, or buff-weathering, calcareous strata (in which the 'Red Stratum' of authors occurs) and holds a conspicuous fauna of brachiopods, trilobites, annelids, cephalopods, crinoids, etc. It is followed downward by

4. THE MCADAM FORMATION, which is characterized by dark gray or black fine-grained carbonaceous and oft times splintery shales holding a lamellibranchiate fauna in the upper half of the shale and graptolites in the lower half.

A number of thin lenticular sheets of impure light gray limestone abound in brachiopoda.

5. THE ARISAIG FORMATION. At the base of the Silurian succession, along the Arisaig shore, there occur buff-weathering fine-grained and compact indurated sandstones and shales holding corals (chiefly *Streptelasma*) brachiopods, trilobites, gastropods, etc. These are associated with black carbonaceous and graptolitic shales. The term *Arisaig formation* is suggested and proposed for the lowest Silurian horizon or formation in the section as developed at Beech-hill Cove. The term *Silurian* is here used in the restricted sense as equivalent to the Upper Silurian of Murchison. These formations tabulated would give the following arrangement :

System.	Formation.	Strata.
Devonian.	Knoydart.	Red shales and sandstone, marls and gray sandy shales with tufaceous layers.
Silurian.	Stonehouse.	Red shales and mudstones, with occasional thin bands of limestone.
	Moydart.	Greenish-gray and whitish colored impure limestones.
	McAdam.	Black carbonaceous shales and mudstones.
	Arisaig.	Buff-weathering sandy shales and sandstones, calcareous layers and black carbonaceous shales.

The amount of unconformity, if any, between the Stonehouse and Knoydart formations, *i. e.*, between the Devonian ('Old Red Sandstone') and the Silurian is a point of considerable importance and interest which will receive careful attention. H. M. AMI.

INFLUENCE OF LIGHT ON THE LENGTH OF THE HYPOCOTYL IN INDIAN CORN.

IT is well-known that in vegetating plants of Indian corn, wheat and other cereals, the first node of the stem is found near the surface of the ground, regardless of the depth at which the seed was planted. If the seed is deeply planted, the hypocotyl elongates above the seed proportionally lifting the node almost to the surface. If the seed is planted shallow, on the other hand, the node is found at about the same depth.

That the checking of the elongation of the hypocotyl is due to the influence of light is strikingly shown by an experiment recently conducted in the laboratory of the Wisconsin Agricultural College. Kernels of Indian corn were planted by a number of students in galvanized iron seed pans nearly filled with garden loam, after which the pans were kept covered with close-fitting tin covers until the plantlets began to appear when the covers were removed.

In all plantlets which appeared above the soil before the cover of the seed pan was removed, the first node is above the soil, as is clearly shown by the fact that this node bears the cotyledon, while in those that have since appeared, the first node is just at the surface or below it. E. S. GOFF.

UNIVERSITY OF WISCONSIN.

CURRENT NOTES ON PHYSIOGRAPHY.

ALLEGANY COUNTY, MARYLAND.

THE first volume of a new series of county reports just begun by the Maryland geological survey gives an excellent description of Allegany county, which occupies a central position in the three western mountainous counties. Among nine chapters, treating subjects that range from geology and soils to climate and forests, the physiography of the county is described by C. Abbe, Jr. The three cycles of erosion, characteristic of a great stretch of the

Appalachians, are signalized; the first having witnessed the obliteration of the ancient mountains of deformation in the production of an extensive peneplain; the second, introduced by general uplift, sufficing to produce strips of peneplain on the weaker rocks, but leaving the harder rocks so little worn that their skylines suffice to guide the restoration of the earlier plain; the third, introduced by an uplift of less amount, a relatively brief episode up to to-day, inasmuch as it has permitted only the erosion of narrow valleys in the floor of the weak-rock intermont peneplains. Pauses in the later uplift are indicated by rock terraces on the sides of the young valleys; the recency of the latest uplift is proved by the occurrence of ungraded riffles of hard rock in the beds of the larger streams. The meandering courses of the young valleys in their longitudinal parts are thought to have been inherited from free meanders developed on the open floors of the intermont peneplains, before their upheaval. Several examples of stream adjustment are presented. The report includes many excellent plates; the view of Cumberland and the notch in the even-crested Wills mountains being most characteristic of Allegheny scenery. The report is accompanied by an excellent atlas of six map-sheets; three delicately contoured topographic sheets; and three with an overprint of geologic colors on the topographic base.

The author of the above chapter remarks that the modern method of studying the topography of a district 'seeks, from a study of the outward forms, to discover the reasons for their existence and the processes by which they have been produced. * * * The present physiographic study of Allegany county aims to so present its topography and topographic development as to make clear the reasons why the county has the surface features which characterize it.' A somewhat different wording would have expressed a shade of meaning which is believed to be more appropriate to a physiographic chapter, namely, 'this physiographic study of —— county presents the reasons for the existence of the local topographic forms and the processes by which they have been produced in order that the forms themselves, as they now exist, shall be better known.' The processes of the past are in themselves essentially of a geological nature; they gain a relation to physiography only when they illuminate the facts of the present. Their value to the physiographer lies in the power that they give him to see and to describe the existing facts of topographic form, for physiography is essentially a study of present conditions.

THE PHILIPPINE ISLANDS.

G. F. Becker contributes a 'Brief Memorandum on the Geology of the Philippine Islands' (20th Ann. Rep. U. S. Geol. Surv., pt. ii, 1900, 1–7), which gives another kind of illustration of the point just made regarding the illumination of the present by the past.

Although strictly geological in having to do with past process and time, the essay has a great physiographic value in aiding the imagination to build up a conception of present forms. A strong deformation and uplift of Eocene and older strata was followed by extensive denudation. This was later accompanied by depression, which reduced a large land area to a group of small hilly islets. Volcanic eruptions, making vast additions of material to their denuded and submerged foundation, began during this submergence; then came a general emergence which, with eruptions, has continued ever since; Mayon, one of the most symmetrical cones in the world, having had a violent eruption in 1897. The emergence of the region has revealed coral deposits of the shore waters, which make nearly continuous mantles far up the land slopes, even to altitudes of 2,000 feet. Pauses during uplift allowed the waves to carve sea cliffs and benches, which now take the form of terraces, more or less dissected, as one of the most prominent topographical features of the islands. The last hundred feet of uplift have revealed extensive lowlands, the most valuable part of the archipelago. Considerable areas have been added in deltas, where the mangrove and the nipa palm aid in the deposition of river sediments.

OVERDEEPENED ALPINE VALLEYS.

Kilian, of Grenoble, dissents from the opinion that the overdeepening of glaciated Alpine valleys and the associated discordant mouthing

of the hanging lateral valleys are results of glacial erosion. He concludes that the lateral valleys are the remains of an ancient topography in which the trunk and the branch valleys were accordant; that the lateral valleys, long occupied by névé and ice, have been preserved from erosion, while the trunk valley has been deepened chiefly by stream action during interglacial and postglacial epochs. Overdeepened valleys when thus interpreted are witnesses rather to the conservative action of glaciers than to their destructive action (Note sur le surcreusement ('Uebertiefung') des vallées alpines. C. R. Soc. géol. France. Dec. 17, 1900, 160–162). W. M. DAVIS.

BOTANICAL NOTES.

ELLIOTT'S GRASSES.

THOSE who are fortunate enough to possess a copy of Stephen Elliott's rare two-volume work entitled 'A Sketch of the Botany of South Carolina and Georgia' will be glad to know that Professor Scribner, of the Division of Agrostology of the United States Department of Agriculture, has published a circular (No. 29) giving the results, so far as the grasses are concerned, of a critical examination of Elliott's Herbarium, now in the possession of the College of Charleston, South Carolina. He has been able in this way to verify Elliott's determinations, and to make necessary corrections, the latter due to the fact that in many cases the species had been named previously by foreign botanists, and, also, that many changes in nomenclature have occurred in the eighty or more years which have elapsed since the publication of Elliott's 'sketch.' This herbarium is said to consist of twenty-eight volumes of folios, twelve by twenty-three inches in size, and that part containing the grasses is described as in a 'very good state of preservation.' It is curious that in working over the species, the author (who was assisted by Mr. E. D. Merrill) found it necessary to describe two or more species, viz., *Panicum amaroides* (to be separated from Elliott's *P. amarum*, and hitherto known as *P. amarum minor* Vasey), and *Panicum subbarbulatum* (the *P. barbulatum* of Elliott, but not the *P. barbulatum* of Michaux).

WOOD'S HOLL BOTANY.

THE announcement of the botanical work of the fourteenth season (1901) of the Marine Biological Laboratory, of Wood's Holl, Mass., has just been received. Dr. Bradley Moore Davis, of the University of Chicago, will be in charge again, as he has been for several years past. The session opens July 3d, and extends to August 14th. Work is offered along four lines, viz.: Cryptogamic Botany (algae or fungi, or both); Phanerogamic Botany (the outdoor study of flowering plants; Plant Physiology (experiments and lectures); and Plant Cytology (a laboratory course in methods). Lectures by specialists will be provided as in previous years. A special welcome will be accorded to investigators who desire to carry out special lines of research. Announcements giving further details may be obtained of Dr. Davis.

NEW SPECIES OF NORTH AMERICAN TREES.

IT will surprise many readers to learn that critical botanists have recently discovered many hitherto undescribed species of North American trees. In the January number of the *Botanical Gazette*, Professor C. S. Sargent discusses 'New and Little Known North American Trees,' in which he describes seven new species, viz.: *Gleditsia texana* (a tree one hundred to one hundred and twenty-five feet high, and two and a half feet in diameter, from the valley of the Brazos river, Texas); *Crataegus engelmanni* (fifteen to twenty feet high, and closely related to *C. crus-galli*, from Missouri to Alabama); *Crataegus canbyi* (twenty to twenty-five feet high, also related to *C. crus-galli*, from Delaware); *Crataegus peoriensis* (twenty to twenty-five feet high, from central Illinois); *Crataegus pratensis* (a small tree from central Illinois); *Crataegus submollis* (a large tree hitherto confounded with *C. mollis*, from Maine to Montreal and Massachusetts); *Crataegus dilatata* (a small tree related to *C. coccinea*, from Vermont, Massachusetts and Rhode Island); *Crataegus coccinea rotundifolia* (the *C. rotundifolia* of Moench, one of the commonest of New England forms); and *Crataegus jonesae* (a small tree closely related to *C. coccinea*, from southeastern Maine). Ashe's species, *C. holmesiana*, from Quebec and Ontario to Maine, Massachusetts, New York

and Pennsylvania, is redescribed, as also the original Linnæan *C. coccinea.*

In the February number of *Rhodora* the same author describes thirteen new species of *Crataegus* from the Champlain Valley, principally in the neighborhood of Middlebury, Vermont. The species described are the following: *C. champlainensis* and *C. pringlei*, both of the section 'Molles'; *C. lobulata* (of the section 'Flabellatae'); *C. acutiloba, C. matura, C. pastorum C. pentandra* (all of the section 'Tenuifoliae'); *C. praecox, C. brainerdi* (of the section 'Coccineae'); *C. modesta* (of the section 'Intricatae'); *C. scabrida, C. egglestoni, C. asperifolia* (all of the section 'Anomalae').

SELBY'S HANDBOOK OF PLANT DISEASES.

PROFESSOR A. D. SELBY, of the Ohio Agricultural Experiment Station, has just issued as a bulletin (No. 121) a very valuable pamphlet of seventy pages entitled 'A Condensed Handbook of the Diseases of Cultivated Plants in Ohio.' It discusses in non-technical language the nature of disease, the structure and habits of parasitic fungi, and then takes up alphabetically the cultivated plants of the farm and garden, describing under each the diseases and their effects. Woodcuts are freely used to help the descriptions. A couple of pages are given to formulæ and directions for making different fungicides, and the pamphlet closes with a very suggestive 'spray calendar.' This bulletin must prove to be very useful to the farmers and gardeners of Ohio, and it will be found most helpful, also, to all who are studying the diseases of plants.

CHARLES E. BESSEY.
UNIVERSITY OF NEBRASKA.

SCIENTIFIC NOTES AND NEWS.

GOVERNOR STONE, of Pennsylvania, has appointed Dr. J. T. Rothrock forestry commissioner under the new act, which places the forestry interests of Pennsylvania under the charge of a separate department of the State Government.

GOVERNOR ODELL, of New York, has appointed Dr. Daniel Lewis, of New York City, State Health Commissioner. Dr. Lewis was president of the State Board of Health which has been abolished.

DR. W. W. KEEN, professor of surgery in the Jefferson Medical College, Philadelphia, expects to spend next year in a trip around the world.

PROFESSOR JOHN GRIER HIBBEN, of Princeton University, has returned from his trip abroad and has resumed his work in the University.

THE Institution of Naval Architects has awarded a gold medal to Professor G. H. Bryan, F.R.S., for his paper on 'Bilge Keels.'

IT is stated in *Nature* that the Brussels Academy of Sciences has awarded a gold meda , of the value of six hundred francs, to M. F. Swarts, for a memoir on the subject of carbonates of an element the compounds of which are little known. A similar award has been made to Professor J. Massart, for a memoir on the nucleus of Scizophytes, and the Edouard Mailey prize of one thousand francs, for assistance in the extension of the knowledge of astronomy in Belgium, has been awarded to M. F. Jacobs, the founder of the Société Belge d'Astronomie.

WE also learn from *Nature* that Mr. Vaughan Cornish, whose name is closely associated with the wave-like forms assumed by drifted materials, is now engaged on the Canadian prairies photographing and studying the forms assumed by drifting snow. Thanks to the liberality of the Canadian Pacific Railway Company and the interest evinced in the investigation by Sir William van Horne, Mr. Cornish writes that his work proceeds satisfactorily, and enough has already been done to justify the expedition.

PROFESSOR ERNST HAECKEL is expected to return from Java to the University of Jena at the beginning of the summer semester, when he will resume his regular lectures.

MR. SAMUEL HENSHAW, who has been head gardener of the New York Botanical Garden since its establishment, has resigned on account of advancing years, but is to act as adviser when his services are needed.

DR. F. BIDSCHOF, of the Observatory in Vienna, has been appointed assistant in the Observatory at Trieste.

THE Royal Swedish Academy of Sciences will celebrate the tercentenary of the death of Tycho Brahe by a special session on October 24th. The Academy has also undertaken to issue a facsimile reproduction of the astronomer's great work, 'Astronomiæ Instauratæ Progymnasmata,' which was printed under the author's direction and of which but five copies are known to exist.

THE death is announced of Dr. Robert Pöhlmann, the geologist, curator in the Natural History Museum at Santiago, Chili.

DR. OSCAR SCHLÖMILCH, formerly professor of mathematics at the Technical School at Dresden, died on February 7th, at the age of seventy-eight years.

MR. MAURICE THOMPSON, the eminent poet, critic and novelist, who died recently, did good work as a naturalist. He was originally a civil engineer and was at one time State geologist of Indiana.

ADVICES have been received from Para, Brazil, regarding the death of Dr. Walter Myers, of the expedition from the Liverpool School of Tropical Medicine. The attack of yellow fever followed a prolonged autopsy and Dr. Herbert Durham also contracted the disease. As cable advices to the contrary have not, however, been received, it may be assumed that he recovered.

A CIVIL SERVICE examination will be held on March 26th to fill the position of nautical expert in the hydrographic office, Navy Department, at a salary of $1,000 er annum. The examination will be in pure mathematics, physical geography and navigation.

THE Department of State has received a note from the legation of Sweden and Norway, dated Washington, February 2, 1901, stating that the managers of the Nobel fund have been authorized to correspond directly with interested parties abroad without using the channel of the Ministry of Foreign Affairs at Stockholm.

THE London correspondent of the New York *Evening Post* cables that an extensive collection of Central American land fresh-water shells has been presented to the Natural History Museum by Mr. Frederick Godman, F.R.S. There are nearly ,000 specimens, including types of 70 new species. Mr. Godman also presented a large and important collection of butterflies of Central America, containing 2,500 specimens.

THE Paris Academy of Sciences has decided to award annually in memory of Lavoisier a gold medal for distinguished services to chemistry.

THE fifteenth free lecture course of the Field Columbian Museum of Chicago will be given on Saturday afternoons at three o'clock, as follows:

March 2—'The Kiowa Indians—A Typical Buffalo Tribe,' by James Mooney, Bureau of Ethnology, Washington, D. C.

March 9—'The Hills and Valleys of Wisconsin and eir Life History,' by Dr. E. R. Buckley, Wisconsin Geological and Natural History Survey.

March 16—'The Diamonds of the Kettle Moraine and their ancestral Home,' by Professor William H. Hobbs, University of Wisconsin.

March 23—'The Evolution of Means of Transportation in America,' by Professor Edwin Erle Sparks, University of Chicago.

March 30—'Some Interesting Insects,' by Mr. Edward Benjamin Chope, Assistant in Department of Zoology, Field Columbian Museum.

April 6—'Deep Sea Fishing and Fishes,' by Dr. S. E. Meek, Assistant Curator, Department of Zoology, Field Columbian Museum.

April 13—'The Ancient Pueblos of Arizona,' by Dr. J. Walter Fewkes, Bureau of Ethnology, Washington, D. C.

April 20—'Tour of the Plant World—West Indies,' by Dr. Charles F. Millspaugh, Curator, Department of Botany, Field Columbian Museum.

April 27—'Jamaica—The Princess of the Antilles,' by Dr. Charles F. Millspaugh, Curator, Department of Botany, Field Columbian Museum.

THE second annual banquet of the Sigma Xi Society of the University of Nebraska was held in connection with charter day and mid-winter commencement on February 14th. Afterwards an address was made before the Society by Professor C. C. Nutting, of the University of Iowa, his subject being 'The Conditions of Life at the Bottom of the Sea.'

DR. C. HART MERRIAN, chief of the Biological Survey, lectured before the Linnean So-

ciety of New York on February 28th, his subject being 'The Naturalist on the Coast of Alaska.'

Mr. N. C. Macnamara delivered the Hunterian Oration before the Royal College of Surgeons of England on February 14th, taking as his subject the form of the human skull in relation to the origin of pre-historic man in western Europe.

It is reported that there is a serious outbreak of the bubonic plague in the Khirgiz steppes of western Siberia. Many thousands are said to have already died. The spread of the plague at Cape Town gives apprehension lest the army may be affected, and rumors to this effect are already current.

The last biennial report of the Illinois State Laboratory of Natural History indicates that some valuable investigations have been made in regard to the abundance, distribution and migration of Illinois fishes, their times and places of breeding, their feeding habits and their food preferences. Five stations have been established in the Illinois river for investigation, one in the Spoon river and three in the bottom-land lakes connected with the larger streams. Eighty species of fish were found near Havana, on the Illinois river, the families most characteristic of the region being catfish, suckers and sunfish. There are also a few very abundant species of other families, as the gar, dog-fish, gizzard-chad, yellow bass, sheepshead and carp. A considerable number of collections have been made by high school principals and science teachers and sent to the laboratory in aid of this survey. The laboratory collections of fishes for the last thirty years have been examined and catalogued and rearranged. The collections assorted to the present time are contained in 63 large copper tanks and in 2,827 jars and bottles. A beginning was made last summer in the preparation of colored plates for the report on the fishes of the State. Sixteen plates were finished during the summer, and the color drawings are accurate in detail, true to life in color ,form and attitude. It is the purpose of Dean S. A. Forbes to have illustrated by such plates every species of fish found, and the result will be a more finished series of plates of American fresh-water fishes than has ever yet been published.

UNIVERSITY AND EDUCATIONAL NEWS.

The Chicago Institute of Pedagogy, endowed by Mrs. Emmons Blaine with, it is said, nearly $2,000,000, has been united with the University of Chicago.

Through Mr. Jonathan Bulkley, of New York, Yale University has received $10,000 for the establishment of a fellowship in American history.

President Morley, of Fargo College, North Dakota, is making progress towards collecting the $150,000 necessary to secure the pledge of Dr. Pearson, of Chicago, for $50,000 before the end of the present year.

Mr. Andrew Carnegie has presented $32,500 to the Iron and Steel Institute, London, for the foundation of a research scholarship.

The troubles in the Russian universities appear to be serious, having spread from Kieff to St. Petersburg and Moscow. About 200 Kieff students have been compelled to serve in the army as a punishment for their objecting to one of the professors. It is reported that six of them have been shot for refusing to renew their oath of allegiance to the Czar, but this may be incorrect.

Homer Charles Price, M.S., has been elected to the chair of horticulture and forestry at the Iowa State College of Agriculture and Mechanic Arts. At Wellesley College, Miss Margaret C. Ferguson, B.S., has been appointed instructor in botany and Roxanna H. Vivian, B.A., instructor in mathematics.

Professor Frank Thilly, of the University of Missouri, asks us to state that there is no truth in the report that he had been called to the chair of ethics in Leland Stanford Junior University.

Dr. F. Paschen, of the Technical Institute at Hanover, has been appointed full professor of physics in the University of Tübingen.

Dr. Franz Nissl, known for his work on the histology of the nervous system, has been promoted to an associate professorship of psychiatry at the University of Heidelberg.

*PHYSICAL HISTORY OF THE ROCKY MOUNTAIN REGION IN CANADA.**

IT will now be endeavored to briefly review the orographic changes and the conditions of deposition of which the geological column gives evidence—in other words, to touch in outline the main facts of the physical history of the Rocky Mountain region of Canada.

Regarding the Archean, it need only be said that here, as in most parts of the world, we find, beneath any rocks that can be assigned to the Cambrian in the most extended sense of that term, and apparently separated from these rocks, by a great break and unconformity, a crystalline series or 'fundamental complex' composed of plutonic rocks with highly metamorphosed and vanishing sedimentary rocks in seemingly inextricable association. The similarity of this basal series in different parts of the world is so great as apparently to imply world-wide and approximately contemporaneous conditions, of a kind perhaps differing from any that can have occurred at later periods. The region here described is not, however, an ideal one for the study of these Archean rocks, because of the extreme metamorphism by which much newer formations

* Concluding section of the address of the President of the Geological Society of America, the late Dr. George M. Dawson, read before the Society on December 29, 1900.

have often been affected in it; nor has any series yet been defined that appears here to bridge the gap between the Archean and the strata that may with propriety be attached to the Cambrian.

In the earlier series of deposits assigned to the Cambrian, we discover evidence of a more or less continuous land area occupying the position of the Gold ranges and their northern representatives, and aligned in a generally northwesterly direction. The Archean rocks were here undergoing denudation, and it is along this axis that they are still chiefly exposed, for although they may at more than one time have been entirely buried beneath accumulating strata, they have been brought to the surface again by succeeding uplifts and renewed denudation. We find here, in effect, an Archean axis or geanticline that constitutes, I believe, the key to the structure of this entire region of the Cordillera. To the east of it lies the Laramide geosyncline (with the conception of which Dana has familiarized us) on the west another and wider geosyncline, to which more detailed allusion will be made later.

Conglomerates in the Bow River series indicate sea margins on the east side of this old land, but these are not a marked feature in the Nisconlith, or corresponding series on its western side. Fossils have so far been discovered only in the upper part of the Bow River series, but the prevalence of carbonaceous and calcareous material (particularly in the Nisconlith) appears to indicate the abundant presence of organisms of some kind at this time.

Although no evidence has been found of any great physical break, the conditions indicated by the upper half of the Cambrian are very different from those of the lower. Volcanic materials, due to local eruptions, were accumulated in great mass in the region bordering on the Archean axis to the west, while on the east materials of this kind appear to be mingled with the preponderant shore deposits of that side of the Archean land, and to enter sparingly into the composition of the generally calcareous sediments lying still farther eastward. Where these sediments now appear in the eastern part of the Laramide range they are chiefly limestone, indicating marine deposition at a considerable distance from any land.

The history of the Ordovician, Silurian and Devonian times is very imperfectly known. Marine conditions still prevailed to the eastward of the Archean axis and were probably continuous there, but our knowledge of the region to the west, while as yet almost entirely negative in its character, is not sufficiently complete to enable us to assume the existence of any extensive land area in that quarter. In the Devonian the sea is known to have covered a great area in the interior of the continent, extending far to the north in the Mackenzie basin, and it appears probable that considerable portions of the western part of the Cordilleran region were also submerged, particularly to the north.

About the beginning of the Carboniferous period and thence onward the evidence becomes much more satisfactory and complete. In the earlier part of the Carboniferous, marine sediments, chiefly limestones, were laid down everywhere to the east of the Archean axis, while to the west of that axis (which was probably in large part itself submerged) ordinary clastic deposits, mingled with contemporaneous volcanic materials, were formed, tranquil epochs being marked by the intercalation of occasional limestone beds. It is not clearly apparent from what land the clastic materials were derived, but the area of vulcanism at this time was very great, covering the entire western part of British Columbia to the edge of the continental plateau and, as now known, extending northwest-

ward into Alaska and southward to California.

In the later time of the Carboniferous, however, the volcanic forces declined in their activity, and a great thickness of calcareous marine deposits occurred with little interruption of any kind. The area of land to the eastward was probably increased, for there is some evidence to show a first gentle uprising in the Laramide region at this time (or at least a cessation of subsidence), and no late Carboniferous strata have so far been found there.

No separate record for the Permian has yet been found in this part of the continent, but it must be remembered that, in view of the scanty character of the paleontological evidence, strict taxonomic boundaries can seldom be drawn. At about this time, however, very important changes occurred, for in the Triassic a great part of what is now the inland plain of the continent is found to have become the bed of a sea shut off from the main ocean, in which red rocks with salt and gypsum in some places were laid down. The northern part of this sea appears to have extended into the Canadian region for a short distance, covering the southern portion of the Laramide area. Farther north must have been the land boundary of this sea, and beyond this an extension of the Pacific ocean which swept entirely across the Cordillera. In the southern part of British Columbia, however, this ocean found its shore against the Gold ranges of the Archean axis, where the preceding Carboniferous beds had already been upturned and subjected to denudation. The Laramide region was not affected by volcanic action at this time, but vulcanism on a great scale was resumed in the entire western part of the Cordillera that had previously been similarly affected in the Carboniferous, and the ordinary marine sediments there form intercalations only in a great mass of volcanic products, probably in large part the result of submarine eruptions.

Such definite indications as exist of the Jurassic must, as already noted, be considered as physically attached to the Triassic of the interior plateau of British Columbia. It is probable that the greater part of the Jurassic period was characterized by renewed orogenic movements and by denudation, for when we are next able to form a connected idea of the physical conditions of the region these are found to have been profoundly modified.

It is to about this time that the elevation of the Sierra Nevada and some other mountain systems in the western states is attributed. In the region here particularly described, the Triassic and older rocks of the Vancouver range, or that forming Vancouver and the Queen Charlotte islands, were upturned, while a similar movement affected the zone now occupied by the British Columbia Coast ranges. These may not have been elevated into a continuous mountain system and barrier to the sea, but in any case the ranges then formed were, before the beginning of the Cretaceous period, largely broken down by denudation, so that the underlying granitic rocks supplied abundant arkose material to some of the lowest Cretaceous beds.

It is also probable that subsidence marked the close of the Jurassic, for in southern British Columbia the Pacific of the Earlier Cretaceous extended more or less continuously across the line of the Coast ranges, finding its shore not far to the east of this line. Farther north, although not without insular interruptions, it spread over the entire width of the Cordilleran belt, repeating the conditions found in the Triassic, but with the difference that it extended far to the south along the axis of the Laramide geosyncline, in which rapid subsidence had been renewed. In this early Cretaceous sea and along its margins and lagoons the

massive fossiliferous rocks of the Queen Charlotte islands and Kootanie formations were accumulated and coal beds were produced. Volcanic activity was renewed in some places, particularly near the present seaward margin of British Columbia. Sedimentation evidently proceeded more rapidly than subsidence in many localities and coal-producing forests, largely composed of cycadaceous plants, took possession of the newly formed lands from time to time.

The era of later Cretaceous appears, however, eventually to have been introduced by a marked general subsidence, which, as already noted, carried the Dakota sea entirely across the inland plain of the continent. The distribution and character of the ensuing Cretaceous formations show that the whole southern part of what is now the mainland of British Columbia soon after became and remained a land area, while the sea was more gradually excluded from the northern part of the Cordillera and continued to occupy the area of the Great plains and the present position of the Laramide range. Along the margin of the continental plateau, however, a renewed subsidence was in the main progressing southward and resulted ultimately in carrying the later Cretaceous sediments into the region of Puget sound.

The closing event of this cycle was the deposition of the Laramie beds on the east and in some places to the north, with probably the Puget group and its representatives on the coast, and this was followed by the most important and widespread orogenic movement of which we find evidence in the entire Rocky Mountain region. At this time the great Laramide range, or Rocky Mountain range proper, was produced, rising on the eastern side of the Archean axis along a zone that had previously been characterized from the dawn of the Paleozoic by almost uninterrupted subsidence and sedimentation. That the pressure causing this upthrust of the Laramide range was from the westward is clearly shown by the great overthrust faults in this range. The stability of the old Archean axis, which it may be supposed had previously sustained the tangential thrust from the Pacific basin must at this time have been at last overcome. As a part of the result of this, the chief belt of faulted strata in the Laramide range, originally about 50 miles wide, became reduced in width by one-half. How rapidly this great revolution may have occurred we do not know, but it probably did not occupy a long time from a geological point of view, and the Laramide range, as first produced, may very possibly have attained a height approaching 20,000 feet.* The thickness of stratified rocks in the geosyncline was at the time probably more than 40,000 feet.

It is difficult to determine to what extent the Archean axis with the Gold ranges and other preexisting mountains was affected at this period of orogenic movement, because of the absence of the newer formations there, but it seems probable that no very important change took place. Farther west, however, the great zone of Coast ranges was elevated, and the corrugated and vertical Cretaceous beds, met with even on their inland side, show that large parts of the Interior plateau of British Columbia and of the country in line with it to the northward were flexed and broken. Similar conditions are found to have affected Cretaceous rocks of Vancouver and the Queen Charlotte islands, of which the

* This refers particularly to the better known region near the Bow pass. See Annual Report, Geol. Surv. Can. (N. S.) Vol. II., p. 31 D, and *Am. Jour. Sci.*, Vol. XLIX., p. 463. The base of the mountains may at this time have been nearly at sea level, or 4,000 feet lower than at present, while the actual height at any time attained would depend upon the rapidity of uplift relative to denudation. The total height of folded strata is estimated at from 32,000 to 35,000 feet.

mountain axis, previously in existence, was evidently greatly increased in elevation.

The Laramide geosyncline has already been particularly referred to and allusion has been made to the now well recognized fact that by such zones of continued subsidence and deposition the lines of most mountain systems have been determined. To the Laramide geosyncline here, the mountains of the Archean axis—the Gold ranges—stood in much the same relation as the Archean western border of the Wasatch to the Laramide geosyncline in Utah (as described by Dana), but on a larger scale.

On the other or western side of this axis, as already noted, I am now led to regard the zone of country extending to the Vancouver range as a second and wider geosyncline with a breadth of about 200 miles, in which a thickness of deposits, perhaps greater than that of the Laramide, but in the main composed of volcanic ejectamenta, had by this time been accumulated. The volume of the Carboniferous and Triassic rocks alone must have exceeded 20,000 feet. It is probable that to this may be added a great thickness of older rocks,* for the circumstance that volcanic action was so persistent here and the amount of extravasation resulting from it was so enormous, implies a recognition of the fact that, along this zone (not far from the edge of the continental plateau) the isogeotherms, with what we may call the plane of granitic fusion, had crept up to a position abnormally near the surface. It is to this probably that we may attribute the apparent absence of Archean rocks in the Coast ranges, or at least the impossibility of defining any rocks of that period there, for these, together, no doubt, with great volumes of later deposits, may be assumed to have become merged in the rising granitic magma, on which strata of Triassic age are now often found lying directly, arrested in the very process of absorption.*

*Several thousand feet of Cretaceous rocks must also be added to this thickness near the line of the present Coast ranges, and the total thickness of deposits in the center of this geosyncline must probably have exceeded 40,000 feet.

When the Laramide revolution occurred, by reason of the increasing tangential pressure from the Pacific basin and the growing failure of resistance of the two great geosynclines of this part of the Cordillera, the Laramide range was produced by the folding and fracture of a very thick mass of beds, of which the crystalline base has not yet been revealed by denudation, while in the western trough an eversion of the axis of settlement seems to have occurred, resulting in the appearance of a granitic bathylite of nearly a thousand miles in length, from which the comparatively thin covering of unabsorbed beds was soon afterward almost completely stripped away by ensuing processes of waste.

This last great epoch of mountain making doubtless left the surface of the Cordilleran belt generally with a very strong and newly made relief, which before the middle of the Tertiary period is found to have become greatly modified by denudation. Chiefly because no deposits referable to the Eocene or earliest Tertiary have been found in this part of the Cordillera, it is assumed with probability that this was a time of denudation. It is further indicated that it was a time of stability in elevation by the fact that the prolonged wearing down resulted, in the interior zone of the Cordillera, in the production of a great peneplain, the base-level of which shows that the area affected stood for a very long time 2,000 or 3,000 feet lower in relation to the sea than it now does. If, however, the Puget beds of the coast are correctly referred to the Eocene, it follows that the coast region was at the same period

*Annual Report, Geol. Surv. Can., Vol. II. (N. S.), 1886, p. 11 B et seq.

only slightly lower than at present, and that the movements in subsidence and elevation between this and the interior region must have been differential in character and very unequal in amount.

As already noted, the earliest Tertiary sediments of the Interior plateau of the Cordillera are referred to the Oligocene. Probably some further subsidence at that time interrupted the long preceding time of waste. This period of deposition was in turn closed by renewed disturbance of an orogenic kind, comparatively slight in amount and local, chiefly affecting certain lines in a northwest and southeast direction. Next came renewed denudation or 'planation,' and this continued until the enormous volcanic extravasations of the Miocene began.

It is not proposed in this place to recapitulate in detail the physical conditions of the Tertiary period, for it has already been necessary to refer to these in connection with the description of the beds themselves, which, because they have not been materially changed since their deposition, really tell their own tale.

It need only be said that, after the Oligocene lake deposits had been formed, disturbed and denuded, new series of lakes were from time to time produced at different stages during the Miocene, their beds now generally appearing as intercalations in volcanic deposits of great mass. Both the coast and the interior region appear to have been subject to these conditions, while the Laramide range stood high, with the inland plain of the continent sloping eastward from its base.

Following the close of, or at least a great reduction in, volcanic activity in the early Pliocene, the interior zone of the Cordillera again assumed a condition of stability for a considerable time, during which wide and 'mature' stream valleys were formed. The elevation of the interior plateau region of British Columbia must then have been about 2,000 feet less than it is at present.* Farther north, the yellow Pliocene gravels of Horsefly river and other places are attributed to this period, and the southern aspect of their contained fossil plants is such as to indicate that, in the given latitude, the height of that part of the interior can not have been much above the sea level.

In the later Pliocence a very marked re-elevation of the Cordilleran region evidently occurred, leading to the renewed activity of river erosion, the cutting out of deep valleys and canyons, and the shaping of the surface to a form much like that held by it at the present day. This elevation in all probability affected the coast as well as the interior, and it would appear that the rivers for a time extended their courses to the edge of the continental plateau.

The excavation of the remarkable fiords of British Columbia and the southern part of Alaska must, I think, be chiefly attributed to the later portion of the Pliocene, although it is quite possible that the cutting out of the valleys may have been begun soon after the Laramide upheaval. The antiquity of these valleys is evidenced by the fact that several comparatively small rivers still flow completely across the Coast ranges in their deep troughs. The fiords are now essentially the submerged lower parts of these and other drainage valleys of the old land, not very materially affected by the later glacial action, important as this has undoubtedly been from other points of view. The valleys of the fiord-like lakes that occur along the flanks of the Archean axis of the interior may probably also be referred to river erosion in the later Pliocene, but if so this mountain region must have been affected by a relatively greater uplift at that time, followed later by a subsidence of its central part. It appears,

* *Trans. Royal Soc. Can.*, Vol. VIII., Sec. IV., p. 18.

however, that the excavation of valleys or gorges like these by rivers, when the slope and water supply are favorable, occurs with such rapidity relative to the wider effects of denudation, as to be almost negligible in any general view of the physical changes of an extensive region or in the accounting of geological time.

There is as yet some difficulty in connecting the later physical changes particularly referred to above with those which have recently come under observation far to the north in the Klondike region. It is probable, however, that the auriferous 'quartz drift' of that region, implying long subaërial decay and stability of level, may be attributed to the early Pliocene; while the river gravels found in the newer and deeper-cut valleys may be assigned to the later Pliocene time of greater elevation. During the Pliocene, and probably until its close, the mammoth, one or two species of bison, the moose and other large mammals roamed northward to the Arctic sea. Then came the Glacial period, with renewed great changes in levels and climate and its own peculiar records and history, which in many respects are more difficult of interpretation than those of more remote periods, because the whole time occupied by them has been relatively so brief. I have elsewhere endeavored to follow this history in detail, and do not propose on this occasion to deal with this latest chapter of the physical history of the Rocky Mountain region of Canada.

In conclusion, what appear to be the most striking points evidenced by the geological record of this northern part of the Cordillera may perhaps be specified as follows:

1. The great thickness of strata accumulated both to the east and west of an Archean axis. In the Laramide geosyncline the strata no doubt actually attained the volume stated. In the western and wider syncline it is not so certain that all the formations in their full thickness were ever actually superposed at any one place or time (for reasons already alluded to), but the volume was probably not less than in the Laramide region.

2. The great proportion of volcanic materials accumulated in the western geosyncline and the recurrence of vulcanism throughout the geological time-scale in this region, resulting in the production of massive volcanic formations in the Cambrian, Carboniferous, Triassic, Cretaceous and Miocene.

3. The recurrence of folding and disturbance parallel to the border of the Pacific basin and the concurrent great changes in elevation of the land relatively to the sea, both continued down to quite recent geological times, the latter even into the Pleistocene.

4. The tremendous energy of denudation, in part due to the events last referred to, but also dependent upon the position of the region on the eastern border of a great ocean, where, in northern latitudes, an excessive rainfall must have occurred at all periods on the seaward mountain ranges. No comparable denuding forces were probably ever operative on the east side of the continent in similar latitudes since the definition of the ocean basins of the Pacific and Atlantic.

GEOLOGICAL SURVEY OF CANADA.

STEREOSCOPIC STUDY OF THE MOON.

IN looking at a terrestrial landscape we see that certain features are distant and others near. We also recognize the extension of objects in three dimensions, so that a tree, for example, is not a mere silhouette, but is perceived in its proper rotundity. The data for these automatic and instantaneous judgments as to distance and form are somewhat complex. The distance of

objects of familiar character is judged in part by their apparent size—the principle of lunar perspective. Distant objects, being seen through more air, have a different color from near objects—the principle of aërial perspective. For objects in the foreground we have two retinal pictures which are sensibly different, and from these the eyes estimate distance—the principle of optical parallax. The judgments arising from optical parallax are automatically combined into judgments of the rotundity or solidity of objects. If the sun shines, many objects show one side illuminated and the other side in shadow, and a shadow is also cast on the ground or on adjacent objects. From long association with judgments arising from optical parallax we have come to infer rotundity from the distribution of illumination and non-illumination—the principle of shadows. Finally, sunlight is scattered and reflected from particles in the air and from objects in the landscape so as to come with modified intensity from many directions, affording partial illumination to surfaces not directly exposed to the solar rays. This partial illumination we have learned to interpret in terms of rotundity—the principle of shades.

When one looks at the surface of the moon through a telescope of high power he sees a landscape from an unfamiliar direction and under unfamiliar conditions. As all the objects are strange, he is not aided by linear perspective. As there is no foreground, he is without the assistance of optical parallax. As the moon has no atmosphere his view is devoid of aërial perspective and of shades. It is true that the moon receives reflected light from the earth and there must also be reflection from lunar cliffs, but these reflected lights are so faint as not to help the seeing of surface details; so far as the eye can determine, the lunar shadow is absolutely black. The observer, being deprived of all other data, has to depend wholly on light and shadow, complete illumination and the entire lack of illumination, for his determination of the configuration of the surface. The sense of sight, having been educated by terrestrial landscapes, is unprepared for the peculiar conditions of the lunar landscape and gives false judgments. Close to the terminator, or sunrise line, where light and shadow divide the field, the eye overestimates the relief and sees the topography as grossly exaggerated as some of the published sketches of lunar mountains. At a distance of 40° or more from the terminator the landscape is practically without shadows, but is diversified by spots of color representing the distribution of the various substances composing the moon's face. These colors, being chiefly light and dark grays, are interpreted by the eye as shades and give an impression of relief no less false than that obtained at the terminator. Along an intermediate zone the general effect as to altitude is substantially true, but it can hardly be doubted that many details of form are misconceived.

Professor W. Prinz, of Brussels, has hit upon an ingenious method of avoiding these difficulties and realizing the actual relief. For many years the rotundity of the moon as a whole has been exhibited by means of the stereoscope. The possibility of this depends on libration, which permits us to view the moon from different directions ranging through an arc of about 16°. Two photographs taken in different months and at times properly chosen, and afterward viewed through a properly constructed stereoscope, give the same fulness of relief which we obtain in observing an object at a distance of 9 inches. Professor Prinz has applied the same method to the examination of small portions of the lunar surface greatly magnified, and is thus enabled to see the craters and other details in their natural proportions. To get the best

effect he uses positives printed on glass and moderately illuminated before a specially arranged background. The details are set forth in a small pamphlet* which may be advantageously studied by any one who cares to employ the new method.

It will be observed that the stereoscopic method gives the shapes of lunar features in terms altogether independent of those afforded by telescopic observation. The data furnished by the telescope serve through the principle of shadows; the data of the spectroscope serve through the principle of optical parallax. In the stereoscopic view light and shadow join with local color in defining points and spots, and all points are thrown into proper relation through their parallaxes.

G. K. GILBERT.

A FURTHER STUDY OF THE UNIT SYSTEM OF LABORATORY CONSTRUCTION.

IT is desired to present a series of drawings with the necessary explanations to illustrate the practicability of designing a laboratory on a unit system. These drawings are the outcome of a somewhat careful study of the problem and of discussions with a number of experienced laboratory administrators. They seem to me to demonstrate the entire possibility of constructing a laboratory upon the unit system.

In a previous article, which was published in the *Philadelphia Medical Journal*,† it was maintained that the unit system of Laboratory construction offers real and very great advantages. The advantages are architectural, administrative and for the work of instruction.

The architectural advantages are those of facility and flexibility of design, and those of convenience and economy of construction. It is evident that if the essential requirement is to provide a number of rooms of uniform and moderate size, abundantly lighted and conveniently accessible, then an architect has a comparatively simple problem, which may be carried out in a great variety of designs, and may be readily adapted to special situations and conditions. Such a requirement leaves an architect great freedom as to the exterior of the building, which generally seems as important to the architect as the interior arrangements are important to the owners and users of a building. One indispensable exception to the exclusive adoption of the unit rooms will recur, in probably every case —namely, that of lecture rooms. As regards the construction, I am informed that it would cost less for a building on the unit plan than for one of equal capacity but with rooms of the customary irregularity of size.

The advantages of administration are manifold. Most valuable will prove, I think, the possibility of changing the uses to which the rooms may be put, for not only may the use of a given room for one object or another of a given department be changed, but it may be transferred wholly to a different department, for a unit room as proposed will be equally adapted to the needs of, for example, chemistry, botany, anatomy or physiology—its adaptation to the special needs of any of these sciences depending only upon the furniture put into it. Within a single department a unit room may be applied to many different uses. It will be of convenient dimensions for a class of elementary study, a smaller class of advanced students, or a still smaller number of research men, or of assistants. It can be subdivided into two smaller rooms by temporary partitions. It will be convenient for collections, for a library or reading room, or for a small lecture room. The particular use of any room can be changed

*De l'emploi des photographies stéréoscopiques en sélénologie. Extrait de l'annuaire de l'Observatoire royal de Belgique pour 1901. 27 pages.

† Vol. VI., p. 390, Sept. 1, 1900.

at any time by moving the furniture from one room to another. Another administrative advantage will be the ease with which the laboratory may be enlarged by adding a few more unit rooms, each of which will be as perfectly suited to all the varied requirements of the laboratory as the rooms already in use. Such enlargements may be indefinitely repeated as long as the building space holds out.

The advantages of instruction are those which ensue from having the students divided into small sections. These were considered in the previous article, reference to which has been made above. I venture to repeat what was there said. There are two principal alternatives between which we may choose—the adoption of large laboratories or of a series of small laboratories. The choice is between keeping the students in large classes and dividing them into small sections. Personally I can advocate only the latter choice and must plead for it very strongly. In a large laboratory with 75 or 100 or more students, the noise and confusion are necessarily great, and the detailed supervision of the work is extremely difficult. If the students are subdivided into small sections, these and other difficulties at once vanish, and if each section can be assigned a separate room it may be put under the charge of a special instructor, who shall be personally responsible for the work of that section. Thus each assistant can be given a certain independence. The sense of opportunity with the accompanying responsibility will tend to improve the quality of his teaching. He can be directed to carry his section over a certain part of the subject in a given time and left free to accomplish the result. If the section is small enough the work can be interrupted for an explanation, a direction or a quiz, and the students will ask more and better questions than in the large laboratory, where the many listeners embarrass them, and where they may not find always the same instructor at hand. Finally, the instructor can learn the personal qualities and needs of the men in a small section and establish personal relations with the individuals. It should never be forgotten that such personal relations are most important factors in efficient teaching. It might be urged against the position here taken that the class could be divided into sections in a large room, but my experience convinces me that such a scheme is utterly impracticable. The advantages of moderate sized rooms for all advanced work and for investigations of every kind are so commonly admitted, that their justification by argument is uncalled for. The unit rooms should be therefore of suitable size for these purposes also.

Assuming now that the unit system is desirable, we pass on to the consideration of what may be the best dimensions. The problem resolves itself into three questions:

First, What is the best unit space to allow for each student?

Second, What is the most convenient maximum number of students to assign to a single room?

Third, What additional space must be provided in each room for passages, sinks, shelves, etc., so as to permit it to be fully equipped for the class work?

Let us now consider these questions in the order given.

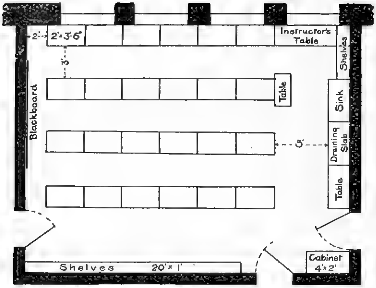
First. The unit space required for each student. In the previous article twenty square feet was suggested as a preliminary estimate, or an area four by five feet. Since then a number of laboratories have been measured, and the relative advantages of various unit areas considered. It is of course desirable on the one hand to reduce the space reserved for each student in order to reduce the total size of the building required, and on the other hand to give each student ample room to carry on the prac-

tical laboratory work under favorable conditions and without interference from his neighbors. These somewhat contradictory requirements may, it seems to me, be reconciled. The study of the subject has led to the final proposition that we accept as the *unit space three feet six inches by five feet* (3 ft. 6 x 5 ft. 0).

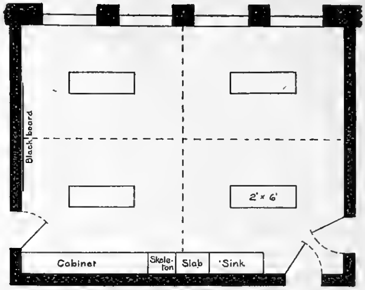
By the metric system such a space would measure 1.067 x 1.524 m., or roughly 1.01 x 1.50 m. These values suggest the possibility of adopting one meter by one and one-half as the unit space. In our space there can be put a table measuring 3 ft. 6 x 2 ft., leaving 3 ft. 6 x 3 ft. clear space for the student to sit or stand at his work, and for the instructor or others to pass behind him. The table will be long enough to permit having, say, two drawers and a locker below them, making on one side a tier about a foot wide, and still leaving space for the student to sit comfortably at the table. There are doubtless many laboratories in this country in which less space is assigned to the individual student than is here advocated, but it seems to me that such crowding and cramping immediately lowers the quality of the teaching and the quality of the studying done. The bad result is due in part to the sheer discomfort of the conditions, but is chiefly due to the inferior opportunities which such crowding entails. When students are close together there can be but little room for laboratory apparatus, consequently the practical work for the students must be to a large extent made ready for them beforehand, so that what should be a laboratory exercise at once becomes barely more than a demonstration. If the students are not crowded, then each one may be supplied with a set of apparatus and be afforded an opportunity to perform himself the complete series of operations necessary to obtain and render available the material or phenomena he is to study. A true laboratory experience is thus placed within his reach, and the instruction is changed from the lower to the higher type. It may be said, therefore, that a fundamental pedagogical principle is involved in refusing to adopt a smaller unit area than above proposed.

Second. The convenient maximum number of students in a single room. This number it is very difficult to determine. It is essentially a question of experience and judgment, and as such, the question is inherently impossible to answer in a conclusive scientific manner. I can therefore only express my opinion that twenty-four is such a convenient maximum number. This opinion is based partly upon general considerations, partly upon an examination of the special requirements of medical instruction. Apparently the common American practise, where large elementary classes are taught, is to provide instructors about in the proportion of one to every twenty-five students more or less. In some universities, where the endowments are ample and the classes moderate in size, the proportion of students to each instructor is less, even in a few cases considerably less. In many universities, on the contrary, the opposite is true. A thorough study of the proportion as it actually exists in the various American institutions of higher instruction would be a valuable contribution to the discussion.

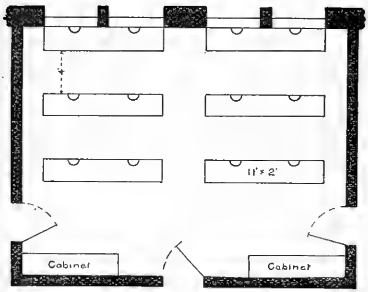
So far as I am aware this study has, unfortunately, still to be made. As regards the particular needs of medical instruction—and it is with this that I am personally most directly concerned—there are special conditions, which greatly facilitate the determination of our convenient maximum. The special conditions, alluded to, are furnished by the work of the dissecting room, because six students are assigned commonly to each subject, hence six forms a natural group in medical studies, and the number put in one room should be a multiple of



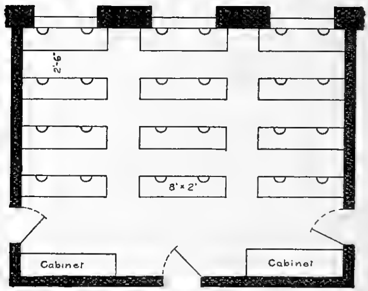
Histology



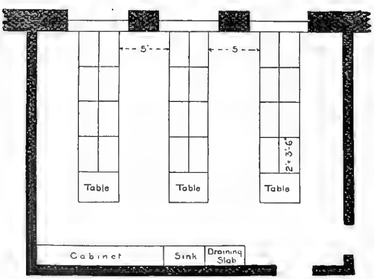
Anatomy



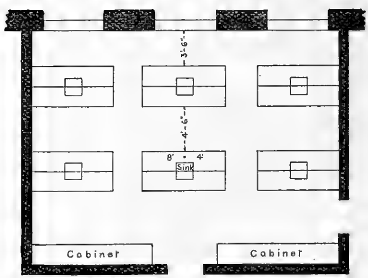
Physiology



Chemistry



Zoology



General Chemistry

six. This leads at once to the number twenty-four, four subjects in one room being convenient and having the advantage of allowing the room to approximate to the square form, which would not be practicable if the number of subjects be fixed at three or five. Twenty-four is close to twenty-five, the approximate number first determined, and being an even number it permits the formation of pairs, which has been found advantageous for certain kinds of laboratory experimental instruction. It appears also that this number commends itself to various professors, who have been consulted as heads of laboratories for histology, physiology, chemistry and pathology. While, therefore, no number can be asserted to be best, it is probably safe to accept twenty-four.

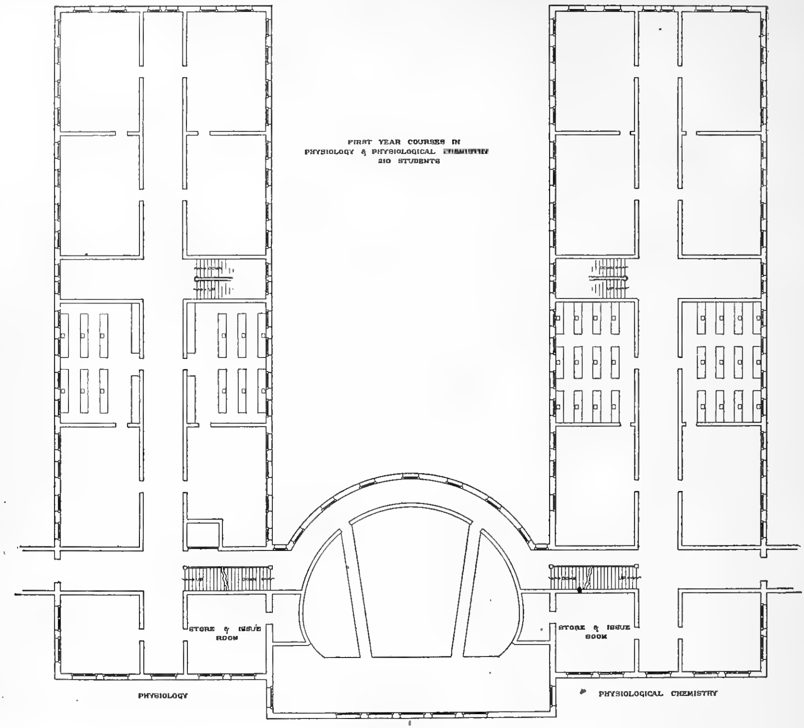
Third. The additional space to be allowed for passages, sinks, cabinets, etc., on the assumption that each room is to have an independent equipment, so that class-work in it can be carried along independently of the work in the other rooms. Measurements of several laboratories led to the supposition that for each student some ten or twelve square feet additional should be allowed. The supposition was then tested by drawing out several rooms, with varying dimensions, with detail plans of the arrangement of the furniture and fittings, until finally eleven square feet was fixed as a desirable allowance.

We are now in a position to calculate the desirable floor area on the following basis: There are to be twenty-four students in each room. Each student is to be allowed for his own use a space 3 ft. 6 by 5 ft., or $17\frac{1}{2}$ square feet, or in all 420 square feet, each student also should be reckoned to require eleven square feet additional for the general use, or in all 264 square feet. Thence $420 + 264 = 684$ square feet required for a room.

A room measuring 30 feet by 23 contains a floor area of 690 square feet (about 10.67 meters by 5.20 m.), which is almost exactly the area desired, exceeding it only by six feet. Rooms of other dimensions have been drawn, but the propositions adopted seemed the best. The thirty-foot side should of course have the windows, and the narrower dimensions, twenty-three feet, correspond therefore to the depth of the room.

I offer herewith six studies of possible arrangements of the *unit room* which the preceding discussion establishes. The six plans are for convenience, though somewhat arbitrarily, named *Histology*, *Anatomy*, *Physiology*, *Chemistry*, *General Chemistry* and *Zoology*. Little need be said about these plans, because they are in the main self-explanatory. Various dispositions of the windows are indicated, but possibly three pairs of double windows would be better than any of the arrangements on the plans. Experience has led many scientific men to doubt whether any architect knows the meaning of the term 'a sufficiently lighted laboratory.' We have all seen inadequately lighted laboratories, but if an over-lighted laboratory exists anywhere in the world, I have yet to hear of it. As to the doors, it may be suggested that, in order to provide for a future possible subdivision of the room, the wall should be so built as to allow two doors, one towards each end of the room; one door space might be built up until needed. Doors are indicated by which adjacent rooms are directly connected. It might be preferable to arrange the rooms in pairs, as indicated by the distribution of the doors in the plans for *general chemistry* and *zoology*.

In *histology* the students are placed in four rows of six each, and a special table is provided for the instructor; a large blackboard is called for on one wall, where it can be easily seen by all the students from their seats. The front edge of a table



STUDY FOR FIRST FLOOR PLAN OF PHYSIOLOGICAL INSTITUTE BY W. T. PORTER.

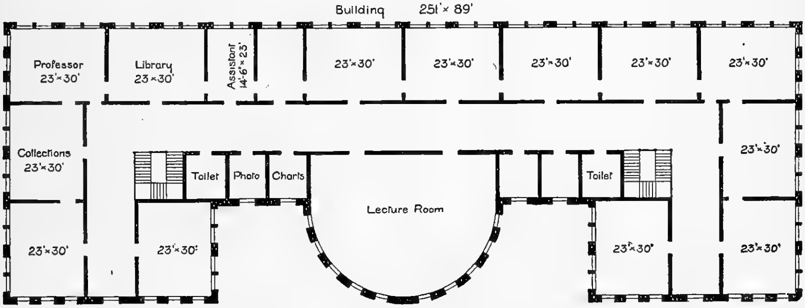
in the fourth row is only fifteen feet from the windows. Every student will be able to obtain unobstructed light for his microscope, especially if the windows are high enough. In *anatomy* there are four dissecting tables, a blackboard, cabinet, sink, etc. In *physiology* the students are assumed to work in pairs, two pairs at each table; hence the design shows six long tables, with a separate sink for each pair of workers. In *chemistry* the tables are eight feet by two, with a separate sink for each student; as the men usually work standing, the tables are placed closer together, and since two students are calculated to a table, twelve tables are provided. The whole or part of one of the spaces marked 'Cabinet' in this plan, as in *general chemistry* may be made into a hood. *General chemistry* shows the more usual grouping of the chemical desks. back to back, with one sink for four desks. Finally *zoology* shows an arrangement which is preferred by many, the tables forming rows at right angles to the line of windows. In many respects this arrangement is favorable. A special advantage is that, without overcrowding, it permits the addition of three tables, upon which appa-

ratus may be placed which is rather for general and common than for personal use.

A candid examination of these six plans will, I hope, convince the reader that the proposed unit-room provides thoroughly convenient, but not excessive, accommodations for twenty-four students, and that the students may be distributed in many differing ways, according to special needs. It has not seemed worth while to pursue these plans further, with a view of showing how a smaller number of advanced workers could be disposed. The solution of such a problem is so simple as not to require illustration. If such a room is to be used for a collection, two cases could be arranged along the side wall, and if there are three windows, two sets of double cases could be placed against the space between the windows and run into the room as do the double rows of tables in the *zoology* plan.

In conclusion, attention is asked to the two studies for a floor plan. The first study is by Professor W. T. Porter, of the Harvard Medical School, to whose generous courtesy I am indebted for the opportunity to publish the plan for the first time. In this study the unit size adopted is 20 x 30 feet, but I have Dr. Porter's permission to state that he considers 23 x 30 feet preferable. In this study there is a central large lecture room connected with the main building, and there are two symmetrically placed wings, which, building space permitting, can be indefinitely extended, whenever enlargement shall become necessary. The second study, by myself, is merely a modification of the first: the size of the unit room is 23 x 30 feet, one room being drawn subdivided for assistant's use; the main building has been lengthened in order to provide small rooms near the lecture hall, and to increase the distance between the wings so as to secure better light; in order not to increase the floor space the wings are drawn shorter. Neither of these studies is to be regarded as more than a preliminary sketch, which needs competent revision and modification

Building 251' × 89'



by a professional architect before it can become practically available. They suffice, however, for the purposes of this article and to illustrate the construction of a laboratory upon the unit system.

CHARLES S. MINOT.

HARVARD MEDICAL SCHOOL, BOSTON,
February 18, 1901.

THE NEW YORK STATE SCIENCE TEACHERS' ASSOCIATION.

THE fifth annual meeting of the Association was held at the University of Rochester, on Friday and Saturday, December 28 and 29, 1900, about two hundred members and others being in attendance. The

officers for the meeting were Charles Wright Dodge, University of Rochester, president; Albert P. Brigham, Colgate University, vice-president; O. C. Kenyon, Syracuse High School, secretary-treasurer.

After brief remarks by the retiring president, LeRoy C. Cooley, of Vassar College, an address of welcome by President Rush Rhees, of the University of Rochester, and the introduction of the president-elect, the opening address on 'The Method of Science and the Public Schools' was delivered in the general session by Professor S. A. Forbes, of the University of Illinois. The speaker held that while the methods of study pursued by the chemist, the physicist and the biologist in their various fields of investigation are by no means identical, there are certain underlying features common to all, and these may be abstracted and generalized and called the method of science. This does not mean mechanical manipulations of tools or of apparatus of any sort, but is essentially psychological in its nature. The study of this method is the study of the scientific mind while engaged in the pursuit of science. The application of the method was illustrated by descriptions of the mode of procedure followed in several recent pieces of investigation. The paper criticized much of the present science teaching in the schools as being unsuited to train the mind of the pupil in the mental operations of independent observation, classification, generalization, deduction and experiment which are the essential features of the scientific method.

The section meetings began on Friday afternoon. In the section of physics and chemistry Professor Henry S. Carhart, of the University of Michigan, gave an address on 'The Place of Physics in a Liberal Education.' As one of the oldest and most fundamental of the sciences, physics should have a prominent place in a general plan of liberal education; its intrinsic interests make it attractive to those who study it; its laws are capable of exact quantitative statement, and it thus furnishes, with the reasoning involved, an excellent instrument of education; its applications to practical and every-day life are so numerous and so important that every intelligent citizen should have a good general knowledge of the subject; it ought, then, to be a part of every high-school course.

Following the paper, Professor Edward L. Nichols, of Cornell University, described a number of devices useful for demonstration purposes in physics. These were (1) an apparatus for showing, in a semi-quantitative way, the expansion of air at constant pressure; (2) floats adjusted to show the phenomenon of maximum density of water; and (3) the torsion balance electrometer.

Before the section in biology, Professor Frederic S. Lee, of Columbia University, spoke on 'The Teaching of Physiology in Secondary Schools.' Dr. Lee advocated a broader view of the subject than most teachers in secondary schools possess. Physiology is the science of the life processes in all organisms, not merely those of the human body. As the basis of all are the vital functions of protoplasm, and of these the pupil ought to have a clear conception. Plain distinctions should be made between gross and minute anatomy on the one hand and physiology on the other, and only so much of structure should be taught as will serve to elucidate function; the idea of physiology proper must be kept paramount. Instruction by practical experiments performed by the pupil or, failing this, demonstrations by the teacher was urged. The number of good laboratory manuals suitable for use in seconday schools now makes such a method entirely feasible. Physiology should follow physics and chemistry in the curriculum. Teach-

ers were urged to inform themselves as to the true status of the alcohol question since most of the statements in the text-books are misleading.

In the same section Professor W. J. Beal, of Michigan Agricultural College, read a paper on 'How shall a Young Person Study Botany?' The paper opened with a very interesting account of the reader's experience as a pupil of Agassiz and of Gray—"The work with Agassiz helped me more than that of any other teacher with whom I ever came in contact, and yet no teacher ever told me so little." The paper advocated the study of plants rather than the study of books about plants; the examination of many related species instead of so many isolated 'types.' The use of the compound microscope ought not to be learned until the latter part of the course. The formation of an herbarium was discouraged. The paper contained a list of most suggestive and interesting topics for individual work for beginners.

Professor W. M. Davis, of Harvard University, addressed the earth science section on 'Practical Experiments in Physical Geography.' Laboratory work for demonstration purposes is most important in this subject, and schools should have proper facilities for it, including sufficient room for practical work, flat roof for sky observations, basement room for experiments with earth and water, as well as an abundant supply of models and charts. The schedule of daily work should be so arranged as to provide for these practical exercises, just as in physics and chemistry. The exercises should include the study of the earth as a globe, the atmosphere, the oceans and the land. The study of the land must be of a kind which will lead pupils to understand what they see in a landscape. Geography ought to serve some other purpose than the education of post-office clerks and express messengers. The study should extend through successive school years, and the speaker suggested that a committee of members of the Association plan a course in the subject to extend through as many years as seem suitable. Stress was laid upon the proper training of the teacher. The preparation of local guides for field work was strongly urged.

The 'Significance and Limitations of Nature' was discussed in the section in nature study by Professor Stanley Coulter, of Purdue University.

Dr. Henry A. Kelly, of the Ethical Culture Schools in New York City, spoke on 'Synthetic Nature Study.' The object of nature work is to interest the child in natural objects and phenomena rather than to give him definite courses in elementary science, to develop a sympathetic appreciation of living creatures and to encourage habits of observation and comparison. Too great emphasis is placed upon analysis in much of our school work, especially in the object lessons. More attention ought to be given to synthetic, creative work. This end may be accomplished by selecting for study topics which are naturally related. Productive results are often obtained by combining nature study with the work in literature.

After the section meetings a general session was held to listen to a discussion of the question, 'What does the College Instructor wish the Scientific Student to know and to be able to do when he enters College?' The speakers were Professors Nichols and Carhart for physics, Coulter for biology, Beal for botany, Lee for physiology and Davis for physical geography. The trend of opinion was to the effect that unless the student could have proper instruction in methods from a competent and well-trained teacher during his high-school course, he had better enter college without any previous study of science.

The evening session on Friday was held

in the new gymnasium at the University. The members of the Association, faculties of the University, the Theological Seminary and the Mechanics' Institute, members of the Academy of Science and of the Engineering Society, together with a number of guests assembled to listen to addresses by Professor J. B. Johnson, of the University of Wisconsin, and Dr. Robert H. Thurston, Director of Sibley College, Cornell University. The former spoke on 'The Scientific Basis of Modern Industry.' By modern industry is meant the entire productive activities of the machine-using nations. Since the introduction of the steam engine the world has made more progress than in all its former history. The steam engine does as much work in a year as all the men in the land could do in a century. Without knowing the real essence of things—gravity, heat, light, electricity—we can know in some degree the laws of their action, and this knowledge is scientific. The effect of this knowledge has been to revolutionize industrial methods. Scientific education is to-day the foundation of all material prosperity, hence industrial education on a scientific basis should receive the most liberal encouragement. Germany has been the first nation to recognize the importance of this work, and now the technical schools of that country are of the same educational rank as the great universities. The applied scientist must be a specialist, and must be given facilities for investigation if discoveries are to be made which shall extend our knowledge of the forces of nature and adapt their actions to human needs.

Dr. Thurston's address was entitled 'The Citizen, his Schools, his Industries, his Life.' Dr. Thurston emphasized the increasing need of every citizen to be educated and to be aided by the State to secure and maintain the best possible position among his fellow men, for individual effort alone avails much less now than when competition was less severe. The material progress of a nation may be measured by its consumption of iron and steel. A better gauge of advancement is the progress of higher education as supplementary to that of the common schools, particularly the development of the modern forms of technical school and the scientific departments of our colleges and universities. A comparison of statistics shows that during the century just closed there was a parallel advance in the development of technical education, the growth of that product of industrial activity which represents permanent wealth, the increase of national wealth, both aggregate and per capita, and the wealth which is secured by the people as wages. The larger educational insitutions of this country now graduate yearly about a thousand students trained in the applied sciences. "The compulsion which has brought about this immense development of higher education has consisted of three main elements: (1) that ability attained, through increased and more widely and uniformly distributed wealth, on the part of the people, to secure higher education, which always marks such progress as we have traced in our material evolution; (2) that constantly growing demand for more generally learned men in the professions, including now the constructive professions; (3) that constantly growing and increasingly intense demand, in all industrial vocations, for a scientific basis for all industries and for highly trained, learned men in all great enterprises and in every system of industrial production. But all these elements of the aggregate compulsion rise out of and accompany the evolution of the modern industrial system, which, in turn, is based upon that progress in civilization through the work of the inventor, the mechanic and the man of science, which is giving us such marvelous accumulations of material wealth, with all its higher accompaniments

in the realms of the sciences, the literatures and the arts, fine, useful and æsthetic." For the past thirty years the demand for mechanical engineers has been increasing at a remarkable rate and is likely to continue. The sciences will more and more become the foundation for all industrial occupations, hence, scientific education should be begun in the preparatory schools, and instruction should be given by teachers who have received adequate training. "One great mind lost to the world through lack of the higher education which it is capable of utilizing is a more grievous loss than sunken fleets. * * * One great exploiter of scientific knowledge counts for an army, for he makes effective an army, saves a country from ruin, raises a nation to previously unimagined heights, confers the comforts of the highest civilization upon the people, or gives his fellow men leadership toward hitherto unexplored realms of wisdom, knowledge and opportunity. The grandest financial expenditures by the state are those which develop new moral, intellectual and physical forces for the benefit of the nation."

After the addresses a reception was given by the Trustees of the University for the Association and guests.

The section meetings were resumed on Saturday morning. In the section in physics and chemistry John S. Shearer, of Cornell University, spoke on the 'Relation between High Schools and College Courses in Physics.' Struck by the fact that in the elementary college courses in physics those students who had received no previous training in the subject were capable of doing quite as good work as those who had taken a preparatory course, the speaker made a careful study of the average standing of the two groups of students and found that those in the second stood only about three per cent. higher than those in the first group. Among the apparent causes of this condition the following were mentioned: Formulæ are memorized without any clear understanding of their meaning; problems are solved by rule of three as a substitute for careful analysis; the student is carefully shielded from the real difficulties of the subject; the idea is too prevalent that physics pertains only to the class-room and the laboratory and has no connection with actual affairs; the habit of self-reliance in testing things by experiment and by deduction from known laws is not developed. In a word, poor teaching is at the bottom of it all.

'The Manual Training of Chemistry' was the title of a very practical paper written by Professor William E. Bennett, of the Rochester High School. The manual training of the trade school is purely utilitarian. It aims to develop manipulative skill to the point of being automatic or reflex, while in the larger and better sense such training should also stimulate mental activity and equip the student to cope with unexpected difficulties. This he can do only if he understands the reasons for each step in the progress of his work. Chemistry, with its delicate operations and manipulations was claimed to be one of the best disciplines to develop the faculties involved.

In a paper on 'The Relative Value of the Qualitative and the Quantitative in Laboratory Work,' Professor W. C. Peckham, of Adelphi College, Brooklyn, held that the greater part of laboratory work in physics should be quantitative in character and that the deductive method of presentation is preferable in high-school work.

Dr. Henry R. Linville presented in the section in biology a paper entitled 'The Framing of a Course in Biology for Untrained Minds: a Discussion of Principles.' The writer stated what he considered should be the main features of such a course and described the work planned for the boys from the 'East Side' in New

York City, outlining the course of study and method of work in zoology in the De-Witt Clinton High School.

'Zoology in Secondary Education' was discussed by Professor Jacob E. Reighard, of the University of Michigan. Professor Reighard held (1) that science teaching in secondary schools should have for its object the developing of scientific method (intellectual) rather than the imparting of information, and that it should be disciplinary rather than technical; (2) that biology does not resolve itself in the final analysis into physics and chemistry; that it is a distinct science with its own principles, and that its intellectual methods are therefore distinctive and different from those of physics and chemistry; (3) that the intellectual methods of the biological sciences are like those employed in the historical, social and other humanistic sciences; (4) that properly conducted biological work in secondary schools therefore affords the best possible training in those intellectual methods which are of the most value to the future citizen, for it trains for citizenship; (5) that the biological sciences are homogeneous, in the sense that there is no necessary sequence of parts, and, aside from practical considerations, their study may be taken up at almost any part and pursued in any order of parts. The paper also dealt with the question, What biology is it possible to teach in secondary schools, and what parts of the subject are of highest training value?

In the earth science section Professor F. M. McMurry, of Teachers College, Columbia University, spoke on 'Controlling Ideas in Geography Work in the Grade,' maintaining that the basal units of geography ought to be taught far more fully than has heretofore been the case, that the proper presentation of these units calls for numerous excursions and the type treatment of topics, that the latter provides for far more frequent and effective reviews than have been customary, and that there is an extensive causal sequence in geography, the beginning point being physiographic and climatic conditions.

Professor Albert P. Brigham, of Colgate University, followed with an address on 'The Personal Equipment of Teachers of Geology and Geography.' The teacher should feel genuine interest in his work and ought to have had as much field experience as possible, including detailed and careful observation and description. Verification in the field of the results obtained by others should also be practised. The acquirement of full knowledge of some one phase of the subject is highly desirable. The economic bearings of the subject ought not to be neglected. Acquaintanceship with other workers in the same field is to be cultivated, and attendance at meetings of scientific societies should be both a duty and a pleasure. The teacher needs also to possess a well-selected library and to be familiar with its contents.

The last paper in the section was by Professor Amos W. Farnham, of the State Normal School, at Oswego, on 'The Purpose of Geography.' It is the purpose of geography to take into account all those physiographic elements, in a related way, which are of use to man, and those, also, which hinder his progress. The child regards the various earth forms of his environment as sources of enjoyment and of interest. Later, he learns the economic importance and the physiographic effect of climatic changes, rainfall, the flow of streams, the amount of sunshine, the effects of drought and so on. G eography cultivates the pupil's intellectual processes, stimulates his emotional nature, and leads him to realize man's dependence upon, as well as to understand his control over, the forces of nature.

In the nature study section, E. Howard Eaton, of the Bradstreet Preparatory School

for Boys, Rochester, spoke on 'Birds in Nature Study.' The rapidly increasing study of birds and bird-life is due, in part, to the general awakening of interest in nature; but there is also a wide-spread feeling that the number of our native birds is decreasing very rapidly, and that it is only by instructing the rising generation in the value of birds and the ways of protecting them that we can hope to preserve the varied, beautiful and highly beneficial species which are disappearing before the onward march of railroads, telegraph wires, plate-glass windows, electric lights, milliners, wood-choppers, ditch-diggers, English sparrows, murderous boys and untutored men. There is, moreover, a great inherent value in bird study. Children are interested in life, and birds are the most alive of all animals. Their highly specialized structure and life activities, their motion, song, language, arts, architecture, community interest, travel and personal traits are highly suggestive to the youthful mind. In this department of nature study there is also a chance of directing the dawning moral sentiments which can not be neglected. To tell children that life is sacred and that nothing that lives should be killed is weakly sensational, irrational and insulting to the ruler of the universe. Boys should be taught why, when and what to kill; not never to kill. The teacher of bird study must know not merely technical biology, but also the natural history of birds, and teach the general structure, relations, habits, food, song, flight, and special adaptations of the different families of birds and the common individuals of each family. Let the boys and girls become acquainted with our bird neighbors and their occupations, and when they know them as well as they do their own friends and recognize them as easily, then they will be good bird protectors.

Mrs. Anna Botsford Comstock, of Cornell University, discussed the subject of 'Nature Study and the Grade Teacher,' describing the work being done in the State in the way of introducing nature study into the schools and mentioning the difficulties encountered in getting the work properly started, owing to the lack of preparation on the part of the grade teachers.

At the closing general session Professor Frank Carney, of Keuka Institute, presented a paper on 'The Moral Value of Science Studies,' and John W. Spencer, of Cornell University, described 'The Work of the Junior Naturalists' Clubs.' These clubs are composed of boys and girls in various parts of the State and were started for the purpose of developing interest in nature. The membership now includes several thousand.

At the business meeting with which the session closed it was announced that forty new names had been added to the membership roll and that the financial condition of the Association was satisfactory. The following officers were elected: *President*, Professor Franklin W. Barrows, Central High School, Buffalo; *Vice-President*, Professor Frank M. McMurry, Columbia University; *Secretary-Treasurer*, Professor A. R. Warner, High School, Auburn.

After adjournment many members took the opportunity to visit Ward's Natural History Establishment, the works of the Bausch and Lomb Optical Company, the Eastman Kodak Company and other places of interest.

Exhibits of scientific apparatus, museum and laboratory supplies, charts, etc., were made by Bausch and Lomb, Ward, Marine Biological Laboratory, Denton Brothers and others.

The proceedings of the meeting will be published in full by the Regent's Office in Albany.

CHARLES WRIGHT DODGE,
Secretary.

SCIENTIFIC BOOKS.

Knowledge, Belief and Certitude, an Inquiry with Conclusions. By Frederick Storrs Turner, B.A. (Lond.). London, Swan, Sonnenschein & Co.; New York, The Macmillan Co. 1900. 8vo. Pp. viii + 484. Price, $2.25.

This is a plain, straightforward bit of work, possessing the good qualities that, as a rule, mark first-hand thinking. Here and there Mr. Turner may be disposed to magnify his office in somewhat *naïve* fashion; but he is so much in earnest that one can forgive him readily.

The problem by which our author has been oppressed may be stated succinctly thus: What is Real Knowledge? In addressing himself to its solution, Mr. Turner distinguishes between what he calls 'abstract' and 'real' knowledge. He finds that the former is common to the many disciplines indicated usually by the generic names science and philosophy. In this connection he says a number of sane things about science, a majority of them, to be sure, quite familiar already. The manner in which he runs amuck among the philosophical dignitaries and their honored idols does him no small credit, if he be aware—which I do not think he is—of the enormities he commits. Some of the references to psychology look suspiciously second-hand, and the cavalier treatment of Wundt hardly reassures one regarding Mr. Turner's insight into contemporary problems and tendencies. Yet, be this as it may, our author suffers nothing on the score of tradition; and, if he contrive to annoy some few, he will, for similar reasons, amuse a great many more.

The portion of his book on which he lays the greatest store on the score of originality, is entitled 'Real Knowledge.' It may be of interest to note the precise import he bestows upon this rather optimistic phrase. For we all remember the proverb about the place where angels fear to tread. 'Real Knowledge,' then, is the "science of ends, of human causality, so far as man is a cause by his own will and according to his own design (351). * * * In all its stages the *end* both is, and leads to, real knowledge. * * * It seems to me that now in this knowledge of ends we have a full and sufficient answer to those psychologists and philosophers who call in question the reality of the first fundamental certitude, that of the Self." (361–62). Thus, knowledge of the Self is 'real knowledge.' Again, "it is not too much to say that the knowledge of our own causal power is on a level with the most certain and the most important knowledge which we possess. This is real knowledge; compared with which mathematics and metaphysics seem shadowy and unsubstantial" (386). With this the 'nescience of science' is to be sharply contrasted. "Science is not a unity nor a system, but merely a general name for a number of separate sciences. All attempts to frame a tenable theory of the universe by means of abstract objective knowledge, or science, are necessarily doomed to failure" (439). On the other hand, positive conclusions are possible, to wit: "The first positive conclusion we have reached is that real knowledge is a state or mode of the conscious being of real living men and women. * * * The second positive conclusion is that this real knowing is a knowing of real persons, real things, real events. * * * The third positive conclusion is that the knowing and the known are united in the reality" (477–78). Such are Mr. Turner's constructive results, so impressive to him that he ends, "not with a feeling of self-complacency, but with joyful confidence in the truth that has been revealed to me (479)."

Needless to tell, all this happens to be one huge ὕστερον πρότερον. Mayhap, human experience must, by the very nature of the case, partake of this character. But a writer who would reveal the inwardness of 'knowledge, belief and certitude' can not be said to have solved his problem by the mere statement of a few among its obvious implications. No doubt, he may accomplish something along such a line—he may be assembling the factors involved. Just because this appears to be Mr. Turner's situation, his interesting book would serve better than some pretentious manuals as an introduction to philosophy for students whose intellectual fates had been committed to a skilled teacher. For it is not given to every author to be so frank when he sees men as trees walking.

University of Michigan.

The Penycuik Experiments. By J. C. EWART. London, A. and C. Black. 1899. Pp. xciii + 177.

Experimental Contributions to the Theory of Heredity. A. Telegony. By J. C. EWART, Proc. Royal Soc., Vol. LXV. 1899. Pp. 243–251.

Guide to the Zebra Hybrids, etc., on Exhibition at the Royal Agricultural Society's Show, York. By J. C. EWART. Edinburgh, T. and A. Constable. 1900. Pp. 51.

About ten years ago there was an agitation in England for the establishment of an institution to experimentally test current theories regarding the processes of evolution. A memorial was circulated, and signed by many eminent persons, but the castle—or rather menagerie—in the air which enthusiasts had built did not descend to solid ground. In the meanwhile, however, certain individuals were laying plans of their own. Experiments in breeding moths had already yielded remarkable results. The experimental method had become fashionable, at least in theory, and it seemed that there were large possibilities before those who had time and money at their command. Under these circumstances it was, perhaps, not remarkable that Professor Ewart, aided and abetted by various friends, should have undertaken to breed equine hybrids to prove the validity or otherwise of the theory of telegony. But if the Penycuik experiments were thus a natural product of the times, they were for that reason the more timely, and all biologists may be thankful to the Scottish professor for having planned them so carefully, and carried them out so satisfactorily.

And now that we have the published results before us, what of telegony? The evidence on which it rested, at least so far as the Equidæ are concerned, is so thoroughly disposed of that it seems almost superfluous to discuss it. Professor Ewart did not start out with the proposition that telegony was absurd, and the statement that he would so prove. On the contrary, whatever he may have thought of the doctrine, he gave it every chance. He also got results similar to those which had been held to prove telegony. Mulatto, a West Highland pony, had a foal by Matopo, a Burchell's zebra. Subsequently Mulatto had a second foal by Benazrek, a gray Arab. This foal, which, except telegony be true, had no zebra blood in its veins, had a number of stripes when a few days old. A figure of it is given, and it certainly has a very zebra-like appearance. At this point a less scientific investigator might have concluded that telegony was proved, and there was nothing further to be said. Not so Professor Ewart. He continued his researches, and in due time was able not only to show that such striping as that of Mulatto's second foal was not uncommon in horses, but also to produce equally striped foals from mares which had never seen a zebra.

In the course of the investigation, many facts of the greatest interest were ascertained. The hybrid between the Highland pony and Burchell's zebra showed a striking likeness to the Somali zebra in the plan of its stripes. This is considered by Professor Ewart to indicate reversion, and in this connection excellent reasons are given for considering that the common ancestor of the various breeds of horses was striped, and that among zebras the Somali species is in many respects the most primitive.

The whole question of reversion resulting from a cross is carefully discussed, and it is suggested when there is a sort of antagonism between the immediate parents or close ancestors, the more or less remote ancestors might contribute more than their normal share to the new individual. That is to say, the two incompatible parents annihilate one another, more or less, like the Kilkenny cats, and the ancestral traits, which otherwise would be crowded to the wall, come to the front. This sounds reasonable enough, but one may hazard a further suggestion that the two parents would contribute the *same* latent ancestral characters, but *diverse* modern ones, and so the characters of their common ancestor might be emphasized. Thus, let A be the characters of the common ancestor, and B and C the characters subsequently acquired by the race represented by each parent. Then the union would be that of AB + AC, which would give A the advantage, if for any reason B and C were less than ordinarily powerful. Dr. Max Standfuss, in breeding hybrid moths (*Entomologist*, 1900, p. 341), has found that the phylogenetically oldest

species appear to be prepotent over those of more recent origin. This may be understood if we represent the union as AA + AB, both contributing the same ancestral characters, and one the same modern ones as the ancestral.

A very interesting point brought forward by Professor Ewart is, that in some cases reversion may lead to a sort of rejuvenescence. For instance, "If there are any puppies in a grossly imbred litter that take after a good ancestor several generations removed, they invariably prove the strongest and best." If there is any truth in the idea that in man physical vigor is correlated not infrequently with a certain rusticity of mind, it may be that the phenomenon is one of a similar kind.

T. D. A. COCKERELL.

EAST LAS VEGAS, NEW MEXICO.

Geological Survey of Canada, General Index to the Reports of Progress, 1863 to 1884. By D. B. DOWLING, B.A.Sc. Ottawa. 1900. Pp. 475.

In the terms of the prefatory note by Dr. G. M. Dawson, Director of the Geological Survey, "the present General Index begins with the volume of 1863 for which an entirely new index has been made, and embraces the succeeding reports to that of 1882–83–84 inclusive. It covers sixteen volumes and two short summaries, making in all 6,585 pages of text to which more than 31,000 entries are given. It thus provides a ready means of reference to practically the entire body of observations published by the Geological Survey up to the year 1884."

From 1885 to the present time, 'Annual Reports' have been issued by the Department, each of which is separately indexed. The 'General Index' just issued forms publication No. 638, of the Geological Survey and contains 475 pages of text divided into three parts, viz :

Part 1. Districts described in the several reports.

Part 2. Special Examination.

Part 3. The General Index.

These include : (1) The reports analyzed geographically and arranged under Provinces, Counties and Districts, so that under any county or district in a province, a list of references to reports, arranged in chronological order, is given. (2) Ores, rocks, minerals or fossils, that have been subjected to assay, analysis, microscopical examination, that were scientifically described. (3) The general index of which the following are the principal points : the arrangement under a reference to a place being usually chronological, while under a subject references will be found alphabetically arranged, or in case of common occurrences, as of iron, fossil, etc., localities may be grouped under provinces.

The 'Reports of Progress of the Geological Survey of Canada' and the 'Annual Reports' of the same contain a vast amount of useful and practical information on the mineral and other natural resources of the Dominion, as do also the maps which accompany these reports, giving in a graphic form the leading geological features of the territory included. This 'General Index' is therefore hailed with delight not only by all who are interested in the resources of the great Dominion as a work which gives ready reference to the various economic products in a series of volumes containing 6,585 pages of text, but also by all students in science who may desire to carry on further researches in the various districts comprised in the reports treated. The amount of time henceforth to be saved in searching for information on the thousand and one points referred to in each of the volumes indexed cannot be over-estimated, and all persons into whose hands this index falls will bless its projector as well as author. An index to all the geological maps referred to in the Reports may be found under the word 'Maps.'

Mr. Dowling's index will also be of special value for bibliographic references, as the work performed by various officers of the Geological Survey from 1866 to 1885 falls under the name of each officer ; and, as the readers of the *Ottawa Naturalist* are aware, in Vol. XIV., No. 6, of that Magazine for September, 1900, Mr. Dowling gave a chronological index to the field work done by the officers of the Survey from its commencement to 1865, so that there is now available for ready reference a complete history of geological work done in Canada from 1843, the year when the Geological Survey of Can-

ada was instituted, to the present time. The price of the above is fifty cents. Copies may be obtained from the Librarian of the Geological Survey. H. M. AMI.

THE CROTONS OF THE UNITED STATES.*

THE United States species of *Croton*, as represented in the principal herbaria of the country, have been monographed by A. M. Ferguson, formerly connected with the Missouri Botanical Garden, now at the University of Texas, whose paper, accompanied by ample analytic keys, and illustrations of all but the most commonly figured species, forms a rather thick octavo paper to constitute a part of the forthcoming 'Twelfth Annual Report of the Missouri Botanical Garden,' where the work was done. In addition to keys and synoptical headings, a citation of necessary synonymy and specimens examined, combined with short but clear descriptions, appears to ensure the easy understanding of the species of a genus that has always afforded a fair number of puzzles to the botanist.

* Ferguson, A. M. 'Crotons of the United States.' (Printed in advance from the Twelfth Annual Report of the Missouri Botanical Garden.) Issued February 16, 1901. Pp. 41, pl. 28.

PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE Proceedings of the 49th meeting of the American Association for the Advancement of Science, edited and published by the permanent secretary, L. O. Howard, make a handsome volume of 500 pages. The volume has as a frontispiece a portrait of the late Edward Orton, who, it will be remembered, died before he was able to give the address of the retiring president at the New York meeting. The volume contains as usual the lists of past officers, the constitution of the Association and lists of members and fellows. There then follow the address of the president, Mr. Grove Karl Gilbert, of the U. S. Geological Survey, and the proceedings of the separate sections, including the addresses of the vice-presidents. The volume concludes with the reports of the secretaries and of the treasurer. It is gratifying to note that the membership at the time of the New York meeting was 1,921, as compared with 1,695 the year before. One rather unexpected result of the change in the time of the meeting from August to June has been a delay in the publication of the volume. Immediately after the adjournment of the meeting the members separated widely for their summer vacations; those who did not go to Europe went into the field, and the secretaries of sections were among them. As a result it was impossible for the permanent secretary to get together the manuscript for a large part of the volume until after the return of the secretaries of sections and other members to their homes in the autumn. The volume was all in print, however, by December and would have been distributed before January 1st except for an accident in the bindery which again delayed the general distribution.

BOOKS RECEIVED.

SCIENTIFIC JOURNALS AND ARTICLES.

The Journal of the Boston Society of Medical Sciences for January 15th contains 'Notes on the Occurrence of *Anopheles Punctipennis* and *A. Quadrimaculatus* in the Boston Suburbs' by Theobald Smith, 'Notes on Anopheles' by Charles S. Minot, and 'Notes on Mosquitoes' by F. P. Gorham. E. R. Le Count presents a 'Report on the Histologic Changes found in the Tissues of Animals Inoculated with Diplococcus Scarlatinæ (Class),' stating that they differ from those noted in man by Pearce in

degree rather than character. A paper of very general interest is that on the 'Action of the Larynx in Relation to the Pitch of the Voice' by Thomas Fillebrowne showing that the larynx should *not* rise with the pitch if one wishes to retain the vocal powers. There are a series of abstracts of papers presented at the Indianapolis meeting of the Public Health Association as follows: 'Observations on Methods for the Detection of *B. coli communis* in Water' by E. E. Irons, 'Variation of the Properties of the Colon Bacillus, Isolated from Man' by W. W. Ford, 'Thermal Death Point of the Tubercle Bacillus and its Relation to the Pasteurization of Milk,' by H. L. Russel and E. G. Hastings, 'A Note on the Disinfectant and Deodorant Properties of Ammonium Persulphide,' by M. P. Ravenel and S. H. Gilliland, and 'An Inquiry into the Rôle of the Domestic Animals in the Causation of Typhoid Fever,' by W. R. Stokes and John S. Fulton.

In *The Popular Science Monthly* for March Simon Newcomb continues his 'Chapters on the Stars' this instalment being devoted to statistical studies of proper motions, concluding that, so far as we can judge, our own system is near the center of the stellar universe. R. H. Thurston considers 'The Law of Substance,' substance being what we are familiar with as 'matter.' Dudley Allen Sargent discusses 'The Height and Weight of the Cuban Teachers' who were in Cambridge last summer, showing that in these points they fall below the average of our own teachers. The reasons for this and the remedy are suggested. Hudson Maxim treats of 'Throwing a High Explosive from Powder Guns' considering that this problem and that of firing high explosives through armor plate have been successfully solved. Harold W. Fairbanks describes 'Pyramid Lake, Nevada' and its curious tufaceous formations, and William H. Hobbs deals with 'The Geologist Awheel' believing that topographical work may be greatly expedited by the use of the bicycle. 'The Formation of Habits in the Turtle' by Robert Mearns Yerkes, describes a series of experiments showing how a turtle learned, or acquired, the shortest route around a number of obstacles to its nest. In 'The Science of Distances,' being the address of the President of the Geographical Section of the British Association, George S. Robertson shows how steam and electricity have shortened the time between distant places and hints at what may be hoped for in the future. Finally Havelock Ellis continues 'A Study of British Genius,' this instalment being devoted to a consideration of the influence of birth and race. Perhaps the most interesting of the brief articles are those discussing the relations between the Government and science.

SOCIETIES AND ACADEMIES.

GEOLOGICAL SOCIETY OF WASHINGTON.

The 110th meeting was held at the Cosmos Club, February 13, 1901. The following papers were presented:

Age of the Coals at Tipton, Blair County, Pennsylvania: Mr. David White.

It was shown that the coals occur in a downfaulted block of coal measure beds surrounded by Pocous strata.

Production of the B. & M. Plant at Great Falls, Montana: Mr. R. H. Chapman.

A view of the reduction works was shown and specimens of the copper products exhibited.

Notes on Two Desert Mines in Southern Nevada and Utah: Mr. S. F. Emmons.

The Delamar mine is situated on the western slopes of the Meadow Valley Range in southeastern Nevada. Its ore-body occurs in a heavy series of quartzite beds of Cambrian age, that strike in a northwesterly direction and dip 23° southeast. The so-called vein is a fracture plane whose strike varies but slightly from that of the enclosing quartzite, but its dip is 70° to 80° to the northwest, or nearly at right angles to the strata. It neither has vein-filling, nor is it mineralized to any considerable extent, but has zones or chimneys of crushed quartzite along it that have been mineralized and carry the ore values. Two granite-porphyry dikes about 30 to 40 feet in width run nearly at right angles to the main fracture, and are crossed by a narrow dike 6 to 10 feet wide of basic lamprophyric rock, so decomposed that its mineral composi-

tion is difficult to recognize. It is sometimes called 'gouge' by the miners. The main fracture plane follows this dike, generally within its walls. The principal ore-chimney is a zone of crushed quartzite around the intersection of this dike and fracture plane with the first granite porphyry dike, where it approaches most closely to the second. All the dikes show evidences of deformation since their intrusion. Smaller ore bodies are found in the hanging wall of the dike to the northward and generally only a few feet in width, while the greater ore chimney, which is divided into four parts by the intersecting and practically barren dikes, has an area of about 200 feet square in horizontal section. The ore is an intensely crushed quartzite, recemented and largely replaced by silica, so that often nothing of the original granular structure of the quartzite is distinguishable. The unoxidized ore shows, besides quartz, only a little finely divided pyrite, very little microscopic chalcopyrite and some telluride in spots. The interesting feature of the mine is the variation in the tenor of its ore, whose values are mainly in gold, the bullion being only 300 fine. In a broad general way it may be said that the values increased downwards to the 700-foot level from $20 to $40 and often to $70, to the ton, small lots running very much higher. From there downwards the values have decreased to about $6 or $8 at the tenth level, and to only $1 to $3 dollars at the fifteenth and sixteenth levels. It is evidently a case of enrichment by gradual leaching down of the precious metals, but as the country is so dry that there is never any moisture in the mine, it must be assumed that this leaching took place in an earlier geologic period, when there was greater precipitation; presumably during the Bonneville period.

The Horn silver mine, in southwest Utah, occurs in a region of very much more complicated geological structure. The Grampian Hills at the south end of the San Francisco Mountains consist of more or less crystalline Paleozoic limestone into which a monzonite mass (locally called syenite) has been intruded in stock-like form. A broad contact zone between limestone and monzonite (locally called andesite) is made up of a dark brown rock, consisting mainly of garnet with many other contact minerals, notably, a white, fibrous tremolite (locally called needle spar).

Opposite the mining hamlet of Frisco, an east and west fault has cut through limestone and monzonite, raising the latter so that it abuts against the former. Along the east base of the hills is a later fault plane, running magnetic north and south, along which more recent andesitic breccias form the hanging-wall, and limestone or monzonite, as the case may be, the foot-wall, the fault plane having a steep dip to the eastward. It is this fault plane that constitutes the Hornsilver vein. The fault fissure or zone varies in width from a maximum of 90 feet down to one or two feet, and has been opened to a depth of 1,600 feet. It is by no means all ore, but consists in great measure of crushed wall-rock, limestone or andesite, as the case may be, but so much altered that its original character is difficult to determine. The ore bodies which have been of great size were largely replacements of this material. It is well known that in its early history, about 1880 to 1885, the mine produced enormous masses of rich silver-lead ores and paid some four millions in dividends in spite of high costs of production, due to its situation in the midst of the desert.

The interesting feature to which the speaker called attention is that whereas neither copper nor zinc was recognized as a constituent of the ore in the upper levels, the main values of late years have been found in a very rich body of copper ore, largely copper glance, extending from 650 down to 750 feet. Moreover, at 500 feet, zinc minerals began to show in small amount, and now in the lower levels the largest ore masses carry 40 to 50 per cent. of zinc, with 6 or 8 per cent. of silver, it being estimated that they have 300,000 tons of this ore in sight. In the deeper part of the mine, while the fault zone holds its width in the main chimney, the ore values have shrunk below the workable point. This is evidently another instance of the leaching down and concentration into the middle levels of the mine of the more soluble salts of copper and zinc, and their reprecipitation in more or less segregated bodies.

The Asphalt and Bituminous Rock Deposits of the United States: GEO. H. ELDRIDGE.

The asphalts, by this meaning the several varieties of purer hydrocarbon compounds, such as uintaite, grahamite, etc., occur in vein form in rocks of Ordovician, Carboniferous and Tertiary ages. They are found in West Virginia, Indian Territory, Colorado, Utah and California. The most remarkable veins are in Utah near the Colorado line, where a maximum width of 18 feet and an uninterrupted length of 10 miles for a single vein have been observed. In California they occur in proximity to the developed oil fields, and the material is here of softer nature than that found in the veins of Utah and elsewhere. Where the veins occur in shales they are irregular and interrupted.

The bituminous rocks embrace both sandstones and limestones. The limestones as yet known are confined to Indian Territory, Texas and Utah; in Texas, in the upper part of the Ordovician, and in Utah, in the Green River Tertiary formation. Those of Indian Territory are conspicuous for their thickness and extent. At one point a bed of 350 feet, impregnated from bottom to top, was observed, having a lineal extent of something over two miles, with considerable variation in the thickness of the bed. Bituminous sandstones are the most generally distributed in the United States, occurring of especial richness in Kentucky, Indian Territory, and in the Coast ranges of southern California. The percentage of bitumen contained in these rocks varies up to a maximum of 14 in the limestones and 20 in the sandstones.

F. L. RANSOME,
DAVID WHITE,
Secretaries.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 335th meeting was held on Saturday evening, February 23rd.

Under the head of notes, B. W. Evermann spoke of the aquatic vegetation observed during the winter at Lake Maxinkuckee, Ill., saying that it remained green and flourishing at a late date. The manner in which the reproductive buds were formed on the species of *Potamogeton* and *Valisneria* was described, and it was stated that it was these buds of the wild celery that were sought after by the coots and ducks.

W. H. Ashmead stated that the examination of the Hymenoptera collected by Trevor Kincaid of the Harriman Alaskan Expedition had raised the number of species known to occur in Alaska from 28 to 318, 195 of which were new. Four European species were noted for the first time as occurring in Alaska, while 30 of the genera had never before been reported in North America.

E. L. Morris exhibited photographs of four new species of *Plantago* stating that these pictures, which were remarkable for their distinctness of outline and detail, were for the purpose of supplying the U. S. National Museum with accurate figures of types which belong to other collections.

F. A. Lucas described 'A Fossil, Flightless Auk' obtained at Los Angeles, Cal., from beds stated by Mr. Dall to be of Upper Miocene, or Lower Pliocene age. The bird was represented by only the proximal part of the humerus, but this showed it to have been somewhat less in size than the Great Auk and more highly specialized, the humerus being shorter, more flattened and more curved, with sharper muscular ridges than the corresponding bone in that species. The name *Mancalla californiensis* was proposed for the fossil auk, and its nearest living relative stated to be the California Murre. The specimen will be described in detail in the Proceedings of the U. S. National Museum. a w. +

W. P. Hay presented a paper 'On the Distribution and Classification of the North American Crayfishes' giving first a brief review of the classification of the Astacoidea in which four families were recognized—Eryonidæ, Homaridæ, Parastacidæ and Astacidæ. In the Astacidæ the three genera *Astacus*, *Cambaroides* and *Cambarus* were described and their distribution commented on.

The American species of *Astacus* and *Cambarus* were then taken up and a few points on the life history of these animals were given. It was stated that the five groups of Faxon are natural and well marked and are worthy of subgeneric rank at least. Contrary to Dr.

Faxon's belief, the author contended that the fifth group of crayfish, including southern United States and Mexican species, is the most generalized and resembles Cambaroides most closely.. This would seem to indicate that the theories of Huxley and Faxon to explain the distribution of the Astacidæ will not hold good and that the original home of the Astacine progenitors was in southern seas and invaded the continents from that direction. It was further stated that the specialization of *Cambarus* is probably much more ancient than the specialization of *Cambaroides*, and that the resemblance between *Cambaroides* and *Cambarus* is accidental and does not indicate a close relationship.

M. B. Waite spoke of the 'Influence of Vegetation on the Sand Formations of the Michigan Lake Shores,' his remarks being illustrated by lantern slides. He showed how dunes may originate by the sand being at first held in check by grass, which grows upward and outward as the sand accumulates, and illustrated the gradual progress inland of dunes and the manner in which the sand moved slowly forward in great waves to overwhelm the adjacent country.

F. A. LUCAS.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 530th meeting of the Society was held February 16, 1901. Mr. R. H. Strother called attention to the fact there are now three processes of making phonographic records that promise to be permanent, so that the early idea of making records of speech for posterity now seems feasible.

Mr. R. A. Harris read a paper entitled, 'A Few Questions in Hydrodynamics.' This reviewed briefly the kinds of problems in liquid wave motion which have been considered in articles and treatises on hydrodynamics. But its chief object was to point out the lack of attention given to oscillations in bodies of water having incomplete boundaries, although a somewhat analogous subject, viz., that of the open organ pipe, had received much attention. The behavior of water in straits is also a neglected subject. The case treated by Airy really applies only to motions in straits not extremely short, and where the bodies connected are comparatively deep. These and other hydrodynamical questions, it was contended, must be investigated before satisfactory progress can be made in the theory of tides.

Mr. J. F. Hayford presented the 'Recent Progress in Geodesy,' referring to the triangulation in progress on the 98th meridian; the connection of the principal United States and European stations by pendulum observations; the connection recently made between several independent systems of precise levels, so that the elevations of some 4,000 places have now been published; and the results of the calculations of the axes of the terrestrial spheroid based on the United States observations. [This paper appeared in SCIENCE for March 8th.] A spirited discussion followed regarding the accuracy of the new and rapid base-line measurements, and the leveling between the Gulf of Mexico and the Atlantic Ocean.

CHARLES K. WEAD,
Secretary.

AMERICAN MATHEMATICAL SOCIETY.

A REGULAR meeting of the American Mathematical Society was held at Columbia University, New York City, on Saturday, February 23, 1901. About thirty persons attended the two sessions. The President of the Society, Professor Eliakim Hastings Moore, occupied the chair. The following persons were elected to membership: Professor John F. Downey, University of Minnesota; Professor F. C. Ferry, Williams College; Mr. H. T. Gerrans, M.A., Oxford University; Mr. Edwin Haviland, Jr., New York City; Professor A. E. H. Love, Oxford University; Mr. V. R. Thyagarajaiyar, Bangalore, India. Two applications for membership were received.

The following papers were presented at this meeting:

(1) Dr. H. E. HAWKES: 'Note on Hamilton's determination of irrational numbers.'

(2) Professor E. B. VAN VLECK: 'On the convergence of continued fractions with complex elements.'

(3) Dr. M. B. PORTER: 'On linear homogeneous finite difference equations, with applications to certain theorems of Sturm.'

(4) Professor L. E. DICKSON: 'Concerning real and complex continuous groups.'

(5) Professor E. O. LOVETT: 'An application of continuous groups to non-euclidean geometry.'

(6) Professor E. O. LOVETT: 'Contact transformations which change asymptotic lines into lines of curvature.'

(7) Professor H. B. NEWSON: 'Indirect circular transformations and mixed groups.'

(8) Mr. W. B. FITE: 'On metabelian groups that cannot be groups of cogredient isomorphisms' (preliminary communication).

(9) Dr. EDWARD KASNER: 'On algebraic potential curves.'

(10) Professor MAXIME BÔCHER: 'Green's functions in space of one dimension.'

(11) Dr. H. E. HAWKES: 'Estimate of Benjamin Peirce's linear associative algebra.'

(12) Dr. G. A. MILLER: 'On holomorphisms and primitive roots.'

(13) Dr. EDWARD KASNER: 'Theorems on collinear lines in space.'

(14) Mr. C. W. M. BLACK: 'Decomposition of a form in n variables in an arbitrary domain with respect to a prime ideal modulus.'

(15) Professor MAXIME BÔCHER: 'An elementary proof of a theorem of Sturm.'

(16) Dr. L. P. EISENHART: 'Surfaces whose first and second fundamental forms are the second and first respectively of another surface.'

(17) Dr. L. P. EISENHART: 'Possible triply asymptotic systems of surfaces.'

(18) Dr. H. F. STECKER: 'On the determination of surfaces capable of conformal representation upon the plane in such a manner that geodetic lines are represented by algebraic curves.'

(19) Professor MAXIME BÔCHER: 'Non-oscillatory linear differential equations of the second order.'

The next regular meeting of the Society will be held on Saturday, April 27th. The Chicago section will meet at the University of Chicago, on Saturday, April 6th.

F. N. COLE,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of the Academy of Science of February 18th, 1901, 23 persons present, Professor J. L. VanOrnum read an address of general interest, summarizing the progress made in engineering during the nineteenth century.

A paper entitled 'Florida lichens,' by Professor P. H. Rolfs, was presented by title.

Professor F. E. Nipher showed two photographic negatives, developed by an ordinary pyro developer. One plate had been exposed in a printing frame for 1,000 seconds at a distance of a meter from a 300-candle lamp. It was then treated for ten minutes in a chromic acid bath having ten drops of an eight-per-cent. solution of chromic acid to three ounces of water. This treatment was in the dark-room. The plate was then developed in the dark-room.

The exposure of the other plate had been equivalent to a tenth of a second at the same distance from the lamp, and was exposed under the same plate. This plate developed normally in a pyro developer, having six drops of bromide and six drops of potassium ferro cyanide, both in ten-per-cent. solutions. The over-exposed plate showed more of detail, but the contrasts were less strong than in the plate with normal exposure. It looked like a slightly under-exposed plate.

When a plate with this exposure is treated with the chromic acid bath while in the light, and is then developed in the light, a positive picture results. The chromic acid bath may be replaced by ten drops of saturated potassium bichromate solution, and four drops of common C. P. nitric acid, to three ounces (90 cc.) of water. There is reason to believe that any camera exposure which was intended to be correct may be developed as a positive in the light by such methods. It is certain that it may be handled as a negative in the dark-room.

Professor Nipher stated that if either a negative or a positive had been started and had resulted in a failure, due to improper treatment, the picture with the fog on the plate might be chemically destroyed by chromic acid, and the picture might be redeveloped in either case either as a negative in the dark-room or as a positive in the light.

It was also stated that one plate had been developed as a superb negative at a distance of a meter from a 300-candle lamp. This case was

very remarkable, because, on account of an accident in the treatment, a failure or a poor positive had been expected. Several repetitions of this treatment had failed to yield this result again.

It is frequently observed that with a strong pyrocatechin developer the picture will start as a negative in the light, and will reach a fair degree of excellence, and then reverse. This is in the nature of an oscillation such as is known in electric discharges. The phenomenon is not observed in a weaker or in a more slowly acting bath. The anomalous case before referred to could hardly be accounted for in this way, because the picture developed very slowly in a normal hydrochinon bath, and grew steadily better until it was sharply defined on the back of the film. This case is still being examined.

A short biographic sketch of the late Charles Pierre Chouteau, a charter member of the Academy, who in its early years, as the western representative of the American Fur Company, contributed many important collections to its Museum, was presented by a committee appointed for that purpose.

Two persons were elected to active membership.

WILLIAM TRELEASE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

A FIELD FOR MOSQUITO THEORISTS. CLIMATIC CONDITIONS ON THE UPPER CONGO.

TO THE EDITOR OF SCIENCE:—The following extracts from letters of Father Grison, a Missionary at Stanley Falls, and Mg'r Roelens, Vicaire Apostolique of the Upper Congo, addressed to the Société Antiesclavagiste of Belgium, may be of interest. G. R. S.

WASHINGTON, D. C.,
February 12th.

At Stanley Falls the climate is very agreeable, but is formidable, as the victims of fever are too numerous. Europeans have very inaccurate ideas of tropical temperatures. I have passed eight years at the equator on the Pacific Coast, and have never seen the mercury above 29° C.

Here the maximum is 32° C. and the nights are deliciously cool. This is our climate all the year.

There is, however, a reverse to this picture. We have frequent tempests of indescribable violence; I have counted in one minute during a diluvial rain and continuous thunder, sixty-six flashes of lightning; and have seen in two hours within a radius of a few hundred meters, ten *coup de foudres.*

Mg'r Roelens at M. Pala, writes:

The work of the Mission allows me little leisure for anything else than an occasional attack of fever.

The fever, however, does not ask if you have the leisure, but imposes it at will, and unhappily, a little too frequently.

Dame fever reigns as mistress of the country.

In the rainy season, from November to May, her tyranny is most severely felt; no one escapes attack; the newly-arrived are most susceptible, but the old residents are not completely immune.

Those who have been resident more than a year are the chosen victims of the terrible hæmaturic fever (Malarial hæmaturic, or 'Swamp fever.') In five years' residence I have had the fever fourteen times! For the last two years, fortunately, it has left me in peace.

Brother Stanislas, who has resided here since 1893, is now sick with it for the twenty-fifth time.

It is an old saying here that the third attack is always mortal.

We, however, have passed the period when our lives are despaired of; this result is due to the treatment we have followed here.

Since 1892 the missionaries of the Upper Congo have applied this treatment to seventy-five cases of this fever, of which five only have been fatal.

Beside this there are no other grave climatic dangers for Europeans. The dysentery, which elsewhere is a serious menace, does not occur here.

I suspect that the English at the south of us find this malady more frequently in their boxes of conserves, and in *la dive bouteille.*

At this moment an epidemic of smallpox is invading the country. It is said here that this recurs every seven years, and attacks all who escaped the previous invasion.

We cannot depend upon the vaccine of Europe, because of the long voyage and the great heat.

I have given it many trials without result.

SHORTER ARTICLES.

ARE THE AUSTRALIAN MARSUPIALIA OF OPOSSUM DERIVATION.

AT the last meeting of the American Association for the Advancement of Science, in June, 1900, the writer presented some reasons in

favor of the view that the Australian Marsupials have been derived from opossum-like ancestors. Since then the opportunity has been afforded of examining the case in greater detail, and it may accordingly be of interest to notice certain of the results obtained.

As nearly every writer who has dealt with the group has observed, the Australian Marsupials exhibit extensive resemblances to Placentals in respect to certain features of their outer organization, notably the adaptive modifications of the teeth and feet. By means of a very reliable, though roundabout method, this fact may be made effective use of in determining the character of the Marsupial ancestors. Thus, by reference to the paleontological history of Placentals, it is possible to recognize the sequence of events in the development of their structural modifications, and from this to infer a similar sequence in the similar modifications of Marsupials. Then, by carefully excluding those forms which show obvious signs of degeneration, it is possible to select from the others those modifications which are primitive or original from those which are secondary or derived.

Such an analysis is easily effected because the Australian Marsupials, notwithstanding their great diversity of form, constitute an extremely simple and homogeneous group. They show no indications of having been derived from more than one ancestral type.

The stem-form is found to have possessed the following characters, or more primitive ones: Dental formula

$$i. \frac{5}{3}\ c. \frac{1}{1}\ p. \frac{3}{3}\ m. \frac{4}{4};$$

upper molar teeth triangular, each with three main cusps and an outer row of incipient styles; lower molar teeth each with an anterior triangle of three main cusps, an antero-external shelf, and a posterior heel with three terminal cusps. Foot with the great toe opposable, but with the other digits normal.

These characters are not found together in any one of the Australian forms, but, with one minor exception,* are exactly reproduced in the American opossums.

* The opossums have four lower incisor teeth.

In addition, it appears entirely probable that other structural modifications of the Marsupial organization are also departures from an opossum type. The anteriorly opening pouch of the kangaroos, wallabies, and phalangers, and the posteriorly opening pouch of the bandicoots appear to be modifications of a type like that met with in the opossums, where the opening of the pouch is directed vertically downwards. This condition has been preserved in the Australian dasyures. Again, it is probable that a scaly prehensile tail, like that of the opossums, has to be ascribed to the Marsupial stem-form, since various grades of an apparently disappearing prehensilism are to be met with in the phalangers.

There is also the significant fact that during the Oligocene period opossums were widely distributed throughout the northern hemisphere and that at a slightly later period opossum-like forms (Microbiotheriidæ) existed in South America. To this may now be added the probability that it was at about the middle of the Tertiary that the Marsupial radiation began. Of the latter there is the following evidence: The most advanced modifications of the teeth and feet in Marsupials (kangaroos) are decidedly primitive as compared with the most advanced modifications of the same structures in Placentals (Ungulates, especially the horses). Furthermore, although the Marsupials possess the representative characters of Placental orders, it is barely possible to separate them, in some cases, into families. Both of these facts indicate that the Marsupial radiation has been of much shorter duration than that of the Placentals, and therefore, if the Placental radiation began in the Cretaceous or early Eocene, the Marsupial radiation, as indicated above, could not have begun before the middle of the Tertiary.

If these indications are reliable, it would appear that the entire Marsupial fauna of Australia has been derived by a comparatively recent adaptive radiation from a single ancestral type, of which the American opossums are the existing representatives.

Naturally the greatest objection to such a view is the fact that there are no opossums in Australia at the present time. This difficulty is, however, quite a superficial one. If we

imagine the opossums to have originally gained access to the region, is it not preeminently fitting that, in establishing the foundation of an extremely comprehensive adaptive radiation, and under the favorable conditions of an absolute freedom from competition, they should have thrown aside their original didelphyid characters? And especially is this conceivable when we realize that the differences of structure separating the opossums from the most primitive of the Australian forms (dasyures) are extremely slight.

However unprogressive the opossums may at first sight appear to be, they are still plastic types. That they are at the present time attempting to radiate in South America is apparent from the numerous subgeneric divisions which it has been found necessary to establish,* and more especially from the fact that one form (Chironectes) has already become completely adapted to an aquatic life.†

The above conception approximates closely the general opinion, expressed by Lydekker,‡ in 1896, that the opossums and dasyures are the descendants of a common ancestral stock, but differs in assuming that these ancestors were opossums, and that they were formerly present in Australia. If we assign to the ancestors of the dasyures characters which would allow them to constitute the Marsupial prototype, they would no longer be Dasyures, but opossums. Ameghino has suggested the South American Microbiotheriidæ as ancestral to the dasyures, and Bernard (Éléments de paléontologie) regards the border as opossums.

B. ARTHUR BENSLEY.

COLUMBIA UNIVERSITY,
November 5, 1900.

WORK AT THE MARINE BIOLOGICAL LABORATORY OF WOOD'S HOLL, 1900.

THE course in physiology should be classified as a kind of research. The same is true in large measure of the course in embryology. In both of these courses, for instance, Dr. Loeb's experiments on artificial parthenogenesis were successfully repeated. Both of these courses are attracting students from medical colleges who feel the need of getting away from the strictly conventional physiology and embryology, into touch with the new lines opening up—in physiology, with the comparative study of biokinetics and in embryology with the new lines of thought introduced by experimental work and by the studies in cell-lineage. Both of these courses, as given here, are largely the outcome of the results of research of preceding years by members of the laboratory, who are themselves concerned in giving the instruction. They therefore represent the spirit of the laboratory along these two lines of investigation.

As regards investigation proper:—In PHYSIOLOGY, Dr. Loeb has continued his experiments on artificial parthenogenesis and has succeeded in inducing the development of unfertilized eggs of Annelids (see a recent number of SCIENCE). Other lines of work in physiology concern the chemical stimulation of nerves, the physiological effects of inorganic salts on the rhythmical activity of living tissues, similar studies on ciliary motion; and work on regeneration by several investigators.

In CYTOLOGY: work on *spermatogenesis* has been carried on by Dr. Montgomery, Mr. Downing and Miss Wallace; on *ovogenesis* by Mr. Arthur E. Hunt, Dr. H. E. Crampton and Dr. C. M. Clapp; on *fertilization* by Dr. Conklin, Miss Katharine Foot, Miss Strobell, Dr. F. R. Lillie, Mr. Martin Smallwood. Dr. E. B. Wilson has brought here his experimental work on fertilization and cleavage in the sea urchin eggs.

In EMBRYOLOGY work has been carried on in various lines: *Annelids* by Dr. A. C. Treadwell and Mr. R. S. Lillie, *parasitic copepods* by Mr. Edward Rynearson, *Cirripedia* by Mr. M. A. Bigelow, *fishes* by Dr. Cornelia M. Clapp, Miss Robinson, Dr. Neal and Miss A. C. Smith, *Monotremata* by Mr. B. A. Bensley, *Histogenesis of gastric glands of Amphibia* by Dr. R. R. Bensley, *Planaria* by Mr. W. C. Curtis, *Nucula* by G. A. Drew, *Parasitic Isopods* by J. R. Murlin.

The work in NEUROLOGY included the following: V. E. McCaskill on nervous system and metamerism of *Hirudo*, Mr. Fling

*Cf. Thomas, O., 'British Museum Catalogue of Marsupialia and Monotremata,' London, 1888, pp. 317–322.

†Cf. Gadow, H., 'On the systematic position of *Notoryctes typhlops*, P. Z. S.,' London, 1892, p. 370.

‡Lydekker, R., 'A Geographic History Mammals,' Cambridge, 1896, p. 55.

on *Lumbricus*, Mrs. M. A. Bigelow on Olfactory nerves of Vertebrates, Dr. Neal on origin of motor nerves in Selachians, Dr. A. D. Morrill on histology of nervous system in planarians, Mr. Yerkes on physiology of pineal eye in lizards, Miss Marion Hubbard on the nervous system of *Dero*.

In Zoology: A monograph on *Arenicola cristata* is under way: The nephridia are being studied from the points of view of anatomy and embryology by Mr. R. S. Lillie, the spermatogenesis by Mr. E. R. Downing, Oögenesis by Mr. Arthur E. Hunt, Organs of circulation by Miss Emma Keith. The first part of this monograph, the embryology, by Dr. C. M. Child, is already published and other parts, including the ones mentioned, are well under way. The zoological studies not already mentioned include work on Coelenterata by Dr. Murbach, on *Hemiptera* by Mr. W. M. Chester, on *Pycnogonida* by Mr. L. J. Cole, on *Nemertea* by Miss C. B. Thompson, on *Pectinatella* by Miss A. W. Wilcox, on *Acmæa* by Miss M. A. Willcox, on *Amphipoda* by Dr. S. J. Holmes, on *Limulus* by Dr. Wm. Patten, on Lamellibranch gill by Dr. E. L. Rice, on *Annelids* by Dr. A. L. Treadwell.

In variation statistics and allied subjects, Miss M. M. Entemann on *Polistes*, Dr. E. C. Edwards on *Synapta*, Dr. H. E. Crampton on Lepidoptera, Miss A. C. Dimon on snails.

In Botany: Cytological work has been carried on by Dr. B. M. Davis, Miss C. M. Derick, Dr. Walter Swingle.

Physiological work has been carried on by Dr. R. H. True and Mr. Roberts. Dr. George T. Moore and Dr. Erwin Smith have also been working in this department.

NOTES ON INORGANIC CHEMISTRY.

From the current chemical journals the following notes are taken:

Professor Fittica still persists in his claims of being able to change phosphorus into arsenic and antimony and gives PN_2O as the true formula of arsenic, and $P_2N_2O_2$ as that of antimony. Christomanos, preparing arsenic, according to Fittica's directions, from commercial phosphorus, tests it without success for the presence of phosphorus and nitrogen, but Fittica replies that this should not occasion surprise, since methods used for testing in one class of compounds often fail when applied to those in which the nitrogen is more firmly united.

The cause of the much discussed poisonous qualities of arsenical wall papers has been shown by Biginelli to be due to the evolution of a gas, diethyl arsin, formed under the influence of the mold *Pencillium brevicaule*, which thrives on arsenic, and develops on arsenical papers.

Some time since reference was made in these columns to the work of H. J. Möller on the protective value of different colored glasses for chemical and drug bottles. His former method was photo-chemical, but he now finds the use of the spectroscope equally satisfactory, and much simpler, a pocket spectroscope answering every purpose. Glasses have a protective value in proportion as they absorb the blue and violet light from the line F to the line H. Dark red glass is the best but most expensive; the dark olive-green of cheap bottles is very satisfactory; dark brown-yellow bottles are effective, but lighter shades of brown, green or blue have little value.

The claims of Desgrez and Balthazard for sodium peroxid as a regenerator of the air in submarine navigation have caused Jaubert to claim priority, as having been at work on the problem for more than three years. According to the latter, however, sodium peroxid has many disadvantages, but he expects in the near future to publish results attained with other substances which are more effective, and cheaper than even compressed oxygen.

It has been noticed at various times during the past four years that the water of the river Rhone exhibits certain reactions characteristic of aldehydes. This is found by Causse to be due to the presence of ferrous oxy-thio-carbonate $FeCO_2S$, which is formed by the combination of carbon dioxid with ferrous sulfid. The latter results from the reduction of sulfates by organic matter. The compound is broken up by distillation, or on standing, with the formation of an ocherous deposit.

The reduction of sulfates in water to hydrogen sulfid has been supposed to be due to the action of Beijerink's *Spirillum desulfuricans*,

but this is questioned by Saltet, who finds that different micro-organisms are concerned in the process, and that the reduction proceeds in stages, as is the case with the reduction of nitrates to ammonia. Saltet has isolated a new micro-organism, *Bacillus desulfuricans*, which reduces sulfates to sulfites, but produces no hydrogen sulfid.

IT has been found by Matignon that metallic magnesium liberates from their oxids not only thorium, cerium and lanthanum, but also praseodymium, neodymium and samarium. Nitrogen, but not argon, is rapidly absorbed by all of these metals. When the last three are obtained from their oxids in the presence of hydrogen, they unite with it to form hydrids, which are dissociated when strongly heated. Moissan finds that the carbid of samarium, SmC_2, can be formed in the electric furnace in minute, transparent, yellow, hexagonal crystals. It is decomposed by water, the chief gaseous product being acetylene, though considerable hydrogen and members of the paraffin series are also formed. In this action it closely resembles the carbid of yttrium.

THE fact that Dewar has found hydrogen to be a constituent of the atmosphere gives much interest to the discovery of Gautier, that hydrogen is formed by the action of water on granitic rocks at temperatures considerably below a red heat. In one experiment a granite rock was heated with phosphoric acid and gave 1,400 cc. of gas per kilo, 916 cc. of which was hydrogen. With water, the quantity liberated is somewhat less. Ammonia is formed at the same time, and Gautier concludes that both these gases are derived from the action of water on nitrids, chiefly iron nitrid, though possibly some of the hydrogen may come from carbides. Matteucci found during a recent eruption of Vesuvius, pieces of rock, coated with ammonium chlorid and iron nitrid, which would seem to show a close relation between these substances.

IN a short paper in the *Berichte*, Giesel confirms the observation of Walkhoff as to the effect of radio-active substances on the skin, similar to that of the Röntgen rays. He placed a celloloid capsule containing a quarter of a gram of radium, under his arm, and in two hours a slight reddening was apparent. In the course of two or three weeks considerable inflammation was present, with darkening, and finally loss of the skin. A similar action was found to take place on the leaves of living plants, and salts, glass and paper were also affected.

J. L. H.

ZOOLOGICAL NOTES.

DR. ANTONIO PORTA, of the Institute of Zoology and Comparative Anatomy at the University of Parma, has lately published in the Proceedings of the Royal Institute of Science and letters of Lombardy his researches on *Aphrophora spumaria* and, in a footnote, he says, "I had already finished the present paper when I received a pamphlet by Professor Morse in which he discusses the formation of the froth in the *Aphrophora spumaria*. It was with genuine satisfaction that I found there a confirmation of observations that I had made. Moreover, I repeated one of his excellent experiments, which leaves no doubt whatever of the fact that the insect emits a liquid only. Placing a larva on a piece of absorbent paper in order to dry it and then upon a glass, if we allow a drop of our saliva to fall upon it, it begins to fill this liquid with air-bubbles."

It is a curious fact that Mr. Morse gave an account of the manner in which the so-called spit-insect makes the froth on grass in his 'First Book of Zoology' twenty-five years ago. German editions appeared in Stuttgart and Berlin, an English edition was also published, and finally the book was translated into Japanese, and yet every general work on entomology has repeated the erroneous ideas regarding the habits of this creature. Even the last volume of the Cambridge Natural History series continues the error. In May of last year Mr. Morse published in the *Popular Science Monthly* an extended account with illustrations explaining more in detail the habits of the larva, and its method of forming the froth and it is to this paper that the Italian naturalist refers.

NOVA PERSEI.

PROFESSOR EDWIN B. FROST writes to the *Astronomical Journal* from Dartmouth College,

under the date of February 25th, in regard to the new star as follows: "This brilliant object attracted my attention at eleven o'clock on the evening of February 22d, before the receipt of the announcement of its discovery by Dr. Anderson. It was at that time to my eye brighter than a standard first magnitude star, and showed a distinct yellowish color, recalling to my mind the shade of *Nova Aurigæ*. It was cloudy here on the 23d, and the spectrum was first examined, between clouds, on the 24th, from $6^h\ 30^m$ to $10^h\ 30^m$ E.S.T. The observations were made with a McClean direct-vision star spectroscope attached to the nine-inch refractor of the Dartmouth Observatory. The general appearance of the visual spectrum was quite similar to that of *Nova Aurigæ*, with the bright components of the doubled lines on the less refrangible side (toward red). The dark components appeared relatively more intense, however, than in case of *Nova Aurigæ*, probably in great part a result of the superior brightness of the present star. The dark band on the more refrangible side of C was especially broad, much more so than in Campbell's drawing of the visual spectrum of *Nova Aurigæ*. Although the spectroscope employed does not permit micrometer settings to be made, the identification would seem to be sufficiently exact of the hydrogen lines $H\alpha$ and $H\beta$, the sodium lines at D, the magnesium group b (in whole or part), and probably the strong line at λ 5016—all these being represented by dark and bright components. Numerous other lines were seen which can not yet be identified. Singularly enough, the helium line D_3 was very faint or absent (the identification of the sodium lines being assumed). This was also the case with *Nova Aurigæ*."

*THE ASSOCIATION OF AMERICAN UNIVERSITIES.**

I HAVE the honor to report upon the second annual meeting of the Association of American Universities, which I attended by your designation as the representative of Columbia University.

The meeting was held at Chicago, February 26–28, 1901. The opening session was held at Chicago University, and the subsequent sessions at the Fine Arts Building on Michigan Avenue. Each of the fourteen institutions represented in the Association was represented by one or more delegates. Each session was well attended by the delegates, and the discussions were practical and earnest. Newspaper reporters and the general public were excluded from the sessions, which, therefore, took on the very helpful form of a conference or a committee meeting. At the close of each session the Secretary gave out to the press such information as he thought proper.

The three topics chiefly discussed were: (1) inter-university migration of graduate students; (2) fellowship; and, (3) the examination for the degree of doctor of philosophy.

Upon each of these topics a short report was presented by a delegate designated in advance for the purpose. Each discussion brought out the details of the practice of the several institutions in regard to each of the matters considered, and while the Association refrained from passing resolutions, certain conclusions were arrived at by what was substantially unanimous consent.

It was held in regard to the first topic that it is wise to promote by all possible means the inter-university migration of graduate students, to the end that they may come under the guidance of teachers of varying points of view, and so may receive the broadest possible introduction to their chosen field of study. The only limitation suggested upon this migration was that circumstances being what they are, it might be unprofitable to the student for it to continue after he had made some progress upon his dissertation.

As regards the question of fellowships, it was held by a majority of those who spoke, that the provision for university fellows in this country is already too large, and that there is danger of stimulating unduly a number of men to go forward to investigation and research who have not the highest and best qualifications for such work. The opinion was expressed that it would be advisable to make some of the fellowships distinctly research fellowships, to be awarded only to students who had already

* Report of Professor Nicholas Murray Butler, delegate from Columbia University to President Low.

taken the degree of doctor of philosophy, and who had, therefore, received their academic equipment for their life work.

In discussing the best type of examination for the doctor's degree, it was held very emphatically that the practice which is growing up in our universities, especially in some of the departments dealing with natural science subjects, of permitting the candidate to pass his examination course by course, as is usual in undergraduate instruction, is a pernicious one, and one which stands in the way of the attainment of the best and broadest scholarship. It was held that the examination for the doctor's degree should, in all cases, be upon subjects and not upon courses of instruction; the underlying principle being that the courses of instruction which a graduate student attends are but a small part of the work which he is supposed to do in order to prepare himself for his examination.

It was developed that there was some difference of practice between the universities as to the formal examination for the degree of doctor of philosophy. On the whole, I think it may be said that it was the opinion of most of those who expressed themselves, that great stress should be laid upon the oral examination at the time when the candidate finally presents himself for his degree, and that if any subordinate examinations are held previous to this time, either upon courses or upon subjects, they should be given very little weight in estimating the capacity of the candidate.

It was voted unanimously to approve the suggestion of the committee appointed by the Council of the American Association for the Advancement of Science, that there be set aside a week to be known as Convocation Week, in order that the various learned societies of the country may arrange to hold their meetings at that time.

It was also voted to print in pamphlet form an abstract of the proceedings of the first and second annual meetings of the Association, and to assess the cost thereof upon the fourteen institutions equally.

The place and date of the meeting of 1902 were referred to the incoming executive committee with power.

The officers chosen for the year were: *President*, Columbia University; *Vice-President*, University of Michigan; *Secretary*, University of Chicago; additional *Members of the Executive Committee*, Harvard University, University of California.

THE NAVAL OBSERVATORY.

SENATOR CHANDLER'S amendment to the Naval Appropriation Bill, providing a Board of Visitors to the Naval Observatory and requiring the Superintendent to be a line officer of the Navy not below the rank of Captain, was, after stout and repeated resistance by the House conferees, at last accepted, with, however, an amendment, consisting of the words 'until further legislation by Congress,' the concluding clause reading: "The Superintendent of the Naval Observatory shall be, until further legislation by Congress, a line officer of the Navy of a rank not below that of Captain." This, of course, indicates that in the opinion of the House conferees further legislation should follow. The bill was finally passed by both Houses without debate on these provisions.

It appears from the following extract from the Washington *Evening Star* of the 8th inst., that the affairs of the Observatory are likely to be kept before the public:

> Charges have been preferred to the Navy Department by Capt. Charles H. Davis, U. S. N., superintendent of the United States naval observatory, against Professor Stimson J. Brown, director of the Nautical Almanac, head of the mathematical branch of the observatory, who is an officer of the navy with the rank of captain. Both officers are well known in naval and scientific circles. The Secretary of the Navy has had copies of the charges laid before Professor Brown, preliminary to the usual procedure of a court of inquiry, which will determine whether the charges are of a character to warrant a court-martial.
>
> It was at first understood that Professor Brown had been placed under arrest by Captain Davis, but it is said in some official quarters that there has been no arrest, and in others it is stated that, at most, the arrest is technical, following the preferring of charges, and in no way involving any restraint.
>
> The papers were first transmitted to Admiral Bradford, chief of the bureau of equipment, who has supervision of the Observatory, and by him they were laid before Secretary Long. The papers are not made public in such cases and, owing to the personal nature

of the controversy, the officials have surrounded the matter with the greatest secrecy.

It can be stated, however, that the charges come under four main heads, viz., that the accused resorted to intriguing methods to bring about the administration of affairs which he desired ; that he made statements as coming from Captain Davis which that officer controverts; that he threatened the superintendent with attacks upon the floor of Congress, and neglect of duty.

For the present the action of the Navy Department awaits the course that Professor Brown may adopt on the copy of the charges which has been laid before him.

SCIENTIFIC NOTES AND NEWS.

WE record with much regret the death of Dr. George Mercer Dawson, director of the Geological Survey of Canada, which occurred on March 2d, after an illness of only two days.

DR. SAMUEL W. STRATTON has been appointed by President McKinley director of the newly established National Bureau of Standards. Dr. Stratton is professor of physics in the University of Chicago, but has, for the past year, had leave of absence to take charge of the Office of Standard Weights and Measures.

THE President has also appointed a Board of Visitors to the U. S. Naval Observatory, in accordance with the provisions of recent legislation, as follows : St. Clair McKelway, of Brooklyn, N. Y.; Asaph Hall, Jr., of Ann Arbor, Mich.; William R. Harper, of Chicago ; Edward C. Pickering, of Cambridge, Mass. ; Charles A. Young, of Princeton, N. J.; Ormond Stone, of Charlottesville, Va.

DR. ROBERT BELL, one of the assistant directors of the Geological Survey of Canada, has been appointed director in succession to the late Dr. George M. Dawson.

MR. J. E. SPURR, of the U. S. Geological Survey, has accepted an invitation of the Turkish Government to make an investigation of the mineral resources of the country.

DR. W. B. SCOTT, professor of geology in Princeton University, expects to leave in May for South America in the interests of the work carried on in Patagonia by several Princeton expeditions.

MR. W. H. FISK, of Durham, N. C., has been appointed assistant State entomologist of Georgia.

SIGNOR MARCONI was one of the passengers on the *Majestic* which left Liverpool for New York on March 6th.

AT the annual meeting of the Hunterian Society, London, on February 13th, Dr. J. Dundas Grant was elected president of the Society. The annual address was given by Mr. John Poland, who gave a retrospect of surgery during the last century.

ON account of ill-health Dr. Frank Russell has been compelled to omit some of his courses in anthropology at Harvard University, and to relinquish others to another instructor. Having been ordered to a more healthful climate he will occupy the year of exile in carrying on archeological investigations in the Southwest.

PROFESSOR GEORGE S. WILKINS, C.E., professor of engineering at the University of Alabama, has been made Chevalier of the Legion of Honor by the French Government for services on the International Jury of Awards of the Paris exposition. Professor Wilkins was expert of the department of civil engineering and transportation for the commissioner general of the United States at this exposition. He was also the official United States delegate to the following International congresses: Tramways, Applied Mechanics, Technical and Industrial Education and Acetylene Gas.

IN memory of the late Dr. Walter Myers, whose life was sacrificed in the study of yellow fever, a chair of tropical medicine has been endowed in the Liverpool School of Tropical Medicine, to be called the Walter Myers' chair. A gravestone will be erected where Dr. Myers is buried in Brazil, and a memorial plate will be placed in the Birmingham Hospital.

DR. JOHN MINOT RICE died at his home in Northboro', Mass., on March 2d, at the age of 68 years. He was a graduate of the Lawrence Scientific School, Harvard University, and was appointed professor of mathematics at the Naval Academy at Annapolis in 1870.

THERE will be a civil service examination for the position of topographic draughtsman in the office of the surveyor general at San Francisco.

The salary is $1,200, and the examination is on geographic projections, mathematics, and topographic drawing and lettering.

MR. ANDREW CARNEGIE has offered the following sums for library buildings, on condition that the cities mentioned shall provide the cities and ten per cent. of the cost of the buildings annually for maintenance: Richmond, Va., $100,000; Montgomery, Ala., $50,000; St. Joseph, Mo., $25,000; Johnstown, N. Y., $20,000; Ashtabula, Ohio, $15,000.

MR. HENRY H. ROGERS, of New York, has presented to the Millicent Library of Fairhaven, Mass., the water-works of that town, yielding an annual income of about $8,000. The Millicent Library was given to the town of Fairhaven in January, 1893, by the children of Mr. Rogers, in memory of their sister Millicent G. Rogers.

BY the will of Dr. Abbott Hodgman, his library is given to the New York Academy of Medicine.

THE Milwaukee Public Museum has just acquired the Rud. J. Nunnemacher collection, containing a large series of Buddhist, Confucian, Taonist and other divinities from China, Japan, India, Burma, Siam and Northern Thibet, in terra cotta, wood, bronze and brass.

We learn from the *Astronomical Journal* that Mr. A. F. Lindemann, of Sidmouth, England, has placed means at the disposition of the *Astronomische Gesellschaft* to be administered by a committee consisting of H. Seeliger, E. Weiss, G. Müller and H. Kreutz for the purpose of accelerating the work of calculation of comet-material from ancient times to the middle of the nineteenth century. The conditions are briefly as follows: An average amount of 100 Marks (about $24) will be paid for definitive calculation of the orbit of one of these comets, the award being lower for those requiring a relatively small amount of time and higher for those presenting especial difficulty. The award will be made to the first calculation which sufficed the requirements of a definitive computation, but may be divided in case of simultaneous determinations. The committee will decide in each case whether the requirements are met and the amount of payment. A list of these comets, some seventy in number, may be obtained from Dr. Kreutz, who should be communicated with, in order that duplicate calculations may be avoided.

THE officers of Section D — Mechanical Science and Engineering—American Association for the Advancement of Science, Professor Henry S. Jacoby and Mr. William Harry Jacks, have issued a circular in regard to the Denver meeting. It reads in part.

The subjects which are appropriate for the Section relate more especially to the application of science and of scientific methods to the various engineering problems.

It has been suggested that short papers be presented, giving information regarding the following questions: Have you any experimental data which either confirm or throw doubt upon formulas or constants hitherto generally received? Have you any data upon subjects hitherto considered doubtful, as for example, the strength of unstayed surfaces? What subjects should engineering laboratories undertake to investigate with a view to obtaining data which will be of general importance, and how would you propose to make such tests (including a description of the apparatus)?

It is hoped that many brief résumés of investigations or experiments relating to different subjects of interest to the Section may be offered for this meeting, and that the support of the Section will be shown by the offer of a larger number of appropriate papers than usual, especially by the Western members who have long urged a meeting in the far West.

THE fifth annual meeting of the New York State Audubon Society was held in the American Museum of Natural History on the afternoon of March 8th. Addresses were announced by Dr. Frank M. Chapman of the Museum, Dr. T. S. Palmer, assistant-chief of the U. S. Biological Survey and Mr. Charles R. Skinner, State Superintendent of Public Instruction.

IN order to aid in the extension and further equipment of the Scientific Department, of Manhattan College, New York City, Dr. J. M. Ferrer and a committee of the alumni society have organized a course of five evening lectures to be given in Carnegie Lyceum during the month of April. They have secured the cooperation of men eminent in their respective departments, as will be seen from the following syllabus:

April 10—'Meteors and Meteorites,' by Professor M. F. O'Reilly, D.Sc., London.

April 16—'Development of Artillery in the Nineteenth Century,' by Captain Edward L. Zalinski, U. S. A.

April 22—'Submarine Boats,' by Mr. John P. Holland.

April 25—'The Steam Engine and its Rivals,' by Professor R. H. Thurston, of Cornell.

April 30—'Electric Wave Transmission,' by Professor Michael I. Pupin, of Columbia.

The lectures will be illustrated with stereopticon views. Professor Pupin will further illustrate his lecture by experiments with apparatus used by him in the researches which have led to his recently-announced discoveries in connection with the transmission of speech over long-distance telephones and submarine cables.

AT the International Congress on Tuberculosis to be held in London in July, addresses will be delivered by Professor Robert Koch, Professor Brouardel, dean of the medical faculty of the University of Paris, and by Professor McFadyean, principal of the Royal Veterinary College, London.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. HIRAM SIBLEY, JR., has given Cornell University $85,000, for an addition to the Sibley College of Engineering. It will connect the two present buildings, and give them a frontage on the campus nearly 400 feet in length.

MR. JOHN D. ROCKEFELLER has given $110,000 to Vassar College for the erection of a residence hall similar to the residence hall now being built on the college grounds.

MRS. L. M. PALMER, widow of Dr. A. B. Palmer, for many years professor in the medical department in the University of Michigan, has by the terms of her will left $85,000 to the University, mostly, it is understood, for the benefit of the hospital.

THE District Court at Denver has sustained the will of the late George W. Clayton, who bequeathed most of his estate, valued at more than $2,000,000, to the city of Denver for a college for orphan boys, similar to Girard College, Philadelphia.

THE following statement has been issued in regard to the consolidation of the Chicago Institute with the University of Chicago: "The Chicago Institute is to become a professional school of the University of Chicago, and will include a school of pedagogy and an elementary school and kindergarten. Associated with it will be a secondary or high school, for the present under the leadership of Dr. John Dewey of the university, ultimately, however, to become a part of the Chicago Institute. Colonel Parker is to be the head of the institute, and his successors are to be appointed by the university trustees upon the nomination of the Chicago Institute trustees. With the institute the university receives $1,000,000. Part of this is to be used in furnishing a home and equipment for the institute, and the rest is to be devoted, chiefly as an endowment fund, to the maintenance of the institute. The university expects to expend from its own funds between $10,000 and $20,000 a year for the support of the work."

IT is expected that the Hall of Fame of New York University will be formally inaugurated on May 30th.

OWING to the increase in the number of Assembly districts in the State of New York, Cornell University will hereafter provide 150 free scholarships each year in the place of 128. To educate the 600 students holding these scholarships costs, as President Shurman has pointed out, $180,000, whereas the University received in return a land grant from which the annual income is but $35,000.

DR. W. T. JORDAN, of the University of Tennessee, has been offered the presidency of the University of Alabama.

AT Columbia University the following promotions have been made: M. I. Pupin, professor of electro-mechanics; Marston Taylor Bogert, adjunct professor of organic chemistry; Edmund H. Miller, adjunct professor of analytical chemistry and assaying; S. L. R. Morgan, adjunct professor of physical chemistry; Livingston Farrand, adjunct professor of psychology, and Edward Thorndike, adjunct professor of genetic psychology.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, MARCH 22, 1901.

CONTENTS:

The Condition, Prospects and Future Educational Demands of the Chemical Industries: DR. WM. McMURTRIE 441
Man's Place in Nature: W J McGEE 453
Thomas Benton Brooks: BAILEY WILLIS 460
Scientific Books:—
The Appreciation of Non-Euclidian Geometry: PROFESSOR GEORGE BRUCE HALSTED. *Allen's Commercial Organic Analysis:* DR. G. S. FRAPS. *Hickson on Alcyonium:* J. P. McM 462
Scientific Journals and Articles 466
Societies and Academies:—
New York Academy of Sciences, Section of Biology: DR. HENRY E. CRAMPTON. *Section of Anthropology and Psychology:* PROFESSOR CHAS. H. JUDD. *Section of Astronomy, Physics and Chemistry:* DR. WILLIAM S. DAY. *The Las Vegas Science Club:* T. D. A. C. *Ottawa Field Naturalists' Club:* DR. H. M. AMI 467
Shorter Articles:—
Arsenic Tests: G. E. BARTON. *Preliminary Note on the Embryogeny of Nelumbo:* HAROLD L. LYON 470
Current Notes on Physiography:—
Physiography of New Brunswick; Drainage Changes in Norway; The Assam Earthquake of 1897: PROFESSOR W. M. DAVIS 471
Botanical Notes:—
Trees of the Northern Plains; Shrubs of the Northern Plains; New Edition of the Phytogeography of Nebraska; Botany and Agriculture; Field Ecology in the Rocky Mountains: PROFESSOR CHARLES E. BESSEY 472
The National Bureau of Standards 474
Scientific Notes and News 475
University and Educational News 480

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Pror J. McKeen Cattell Garrison-on-Hudson, N. Y.

*THE CONDITION, PROSPECTS AND FUTURE EDUCATIONAL DEMANDS OF THE CHEMICAL INDUSTRIES.**

IT has been well said that chemistry is an offspring of the nineteenth century. The closing years of the eighteenth century had some glimpses of the wonders the new science had in store, but it remained for the workers of the first decade of the nineteenth to collaborate the results obtained by their immediate predecessors and develop the new truths which finally established the foundation of the glorious structure, which has now grown so great. During this period human necessities were in every way augmented, and particularly in France, claimed to be the fatherland of our science, human ingenuity was sorely taxed to meet these needs.

The struggle to find ways and means stimulated the energies and increased the zeal of the searchers after truth, and the utilitarian quest, as is always inevitable, brought forth results of interest and value above and beyond the actual needs, furnished data upon which are based the most important and fundamental laws of the science and firmly established many of the most important of our industries. The labors of the chemists of the last decade of the closing century had cleared away the

* Address of the President before the American Chemical Society, Chicago, 1900.

haze which surrounded and covered the truths already developed and opened the way for further promotion of the newly-born science. Lavoisier had led, by the introduction of systematic and accurate observation and record, to the crystallization of what had so far concentrated, and his associates, imbued with his spirit and inspired by his genius, were ready and willing to carry forward what he had so nobly begun.

And so the science was launched. How it has progressed during the century now closing has been told in many ways by many men, and the history seems ever new. New laws and new truths found applications in the industries and increased the material wealth, and the industries in turn furnished the material, the data, the incentive, for much of the additional investigation necessary to the development of the further laws.

The activity of the last decade of the last century has its counterpart in that of the century just closing. If the former century established the foundations, the closing century has furnished a superstructure worthy of the great minds who began the work. And whether we consider the later achievements from the side of abstract science, or from that of the applications of the great laws to the material needs, the glory is equally manifest and the wonder no less profound. Whether we consider argon, and helium, neon, krypton and xenon, and the beautiful researches which led to their discovery, polonium and radium, and their remarkable properties, the Röntgen reactions or the liquefied gases, and the attainment of the almost lowest limit of low temperatures; or the wonderful advances in illumination, the production of high temperatures in the electric furnace, the development of new compounds and forms of matter through the aid of these temperatures, the applications of high electric tensions to the production of new reactions, even those most familiar with them must feel the influence of the mighty strides and look into the future with enthusiastic hope.

The interest manifested in the new science in the old world was quickly extended to the new, and it found most active lodgment here. Students and associates of Black in Scotland, Fothergill in England and of the French chemists of the last quarter of the century in Paris started the work, and the names of Rush, Hutchinson, Woodhouse, McLean, Franklin, Rumford, Priestley, Silliman, Hare, Seybert, Norton, Dana and others, will ever find affectionate memories in the minds of the chemists of America. What these men started has been actively developed by those who followed them, until to-day the science and its applications find more actual workers in our country than are to be found in any other country within the bounds of civilization.

The first half of the century had comparatively few men in the United States who could be classed as working chemists. Chemistry had, it is true, been taught in a way in many of the colleges. But systematic work, as we know it to-day in many of the institutions of learning, was practically unknown. Those who felt the special need of, and had a desire for, such instruction were constrained to seek the facilities in other lands, until generous and at the same time practical men, such as Lawrence, Sheffield, Packer, Pardee and Harrison, with enterprising eyes and prophetic vision, saw the advantages to be derived from the further development of the sciences and provided the means whereby well-furnished laboratories could be opened up, and facilities for the profound study of the science could be made possible. But the industrial needs of the country for more exact knowledge of the natural laws extended beyond private munificence, and the national legislatures early recognized

the importance of the better education of those who must manage the rapidly growing industries. The successful efforts of the late Senator Justin S. Morrill and his associates, in securing the enactment of the law which provided for the establishment in each State of an institution for study of agriculture and the mechanic arts, is well known and will always be gratefully remembered. No less important were the efforts of the late Mr. Hatch of Missouri, who labored so earnestly and eventually so successfully for the establishment of the State agricultural experiment stations. There can be no question that nothing has done more for the promotion of the science of chemistry and its applications than the acts of these great captains of industry and legislation. We shall not forget further the wonderful benefactions of Johns Hopkins, Clark, Case, Rose, Rockefeller, Stanford, Schermerhorn, Havemeyer, Fayerweather, Carnegie and others, who have furnished through splendid munificence the magnificent facilities not only for instruction in the science but for abstract research as well.

The science received splendid impulse and inspiration in the meeting at the grave of Priestley in 1874. It brought the chemists of the country, then comparatively few in number, together and established the bond of good fellowship and scientific sympathy, always so necessary to true progress. The most important outcome of this most important gathering was the organization of our own society. In his address delivered at that meeting Professor Benjamin Silliman named eighty-five chemists who had contributed to the advancement of the science in the United States at that time.

In 1876, the American Chemical Society was organized and during the year enrolled 230 members, of which 190 were professional chemists. The impulse given in Northumberland was effective, the example of a few devoted and public spirited men was followed, and though a period of almost fifteen years was requisite to the ultimate firm establishment of the work of the organization and the integrity of the Society itself, the great aims of its founders to secure the harmonious and thorough organization of all the chemists of the country finally prevailed. The Society has continued to increase in membership and influence, until at the present time thirteen local sections have been established in the various parts of the country, all actively working, and at least six of them holding monthly meetings, during all but the summer months, for such scientific intercourse and discussion as cannot fail to be fruitful in the promotion of the science. The roll of membership now contains about 1,750 names, and while this represents but a small proportion of the working chemists of the country, its growth henceforward must be rapid and the hope of the founders fairly realized.

The *Journal* covers annually nearly one thousand pages of matter fairly representative of the work of American chemists, and it has become necessary, because of increased demands for it, to publish an edition of three thousand copies. Its pages are open to communications on all subjects relating to chemistry and its applications, and it is the hope and expectation that the valuable *Review of American Chemical Research* may be accompanied in the near future by abstracts of papers published in the foreign journals, thus furnishing to all our members information regarding the world's works in chemical science and practise.

The progress made in the applications of chemistry in our country can properly and fully be told only in the results of the census now in progress and in hands which promise results of higher value than have ever before been obtained in such work in

this country. We may congratulate ourselves that it has been entrusted to our past president, Dr. C. E. Munroe, whose tastes and training have so admirably fitted him for the delicate and difficult task submitted to him. But we have in the figures prepared by the Bureau of Statistics of the United States Treasury most significant data regarding the progress made during this closing decade of the closing century. From this source we learn that of products classified as chemicals, drugs and medicines, we imported during the year ending June 30, 1890, to the value of $41,601,978, while for the year ending June 30, 1900, this value had become $52,931.055. Most of the materials represented in these figures entered into consumption in industries, based wholly or in part upon the applications of chemistry. We cannot enter into the details of these statistics, but we may consider with interest and profit a few figures relating to some well known industries, and which are instructive in this connection as showing the variations which have occurred during the decade.

Chemicals imported in 1890 and 1900 respectively:

	1890.	1900.
Caustic soda	$1,470,335	$158,793
Soda ash	3,493,288	665,104
Potash, Chlorate of	238,840	102,337
Soda, " "		93,076
Lime, Chloride of	1,385,080	1,461,858
Glycerine	928,935	2,138,670
Alizarine colors	358,882	771,336
Coal tar colors and dyes	1,787,553	4,792,103
Other coal tar prod		397,780
Milk, Sugar of	46,510	399
Glass	7,411,343	4,038,753

The figures indicate enormous growth of the alkali industry in the United States during the decade and show that in this branch of industry we are entirely independent, as regards supplies, of foreign producers. The figures for glycerine show the possibilities of expansion of another industry, while the almost astounding growth of the importations of alizarine and coal tar products and dyes indicates the necessity for the further development and utilization of our own sources of crude materials of like character and the extension of that already begun. The rapid growth of the establishment of the by-product coke ovens reveals great possibilities in this direction, and it must be disappointing if the characteristic enterprise fails to take advantage of these possibilities.

If the importations of chemical products are interesting and indicate great activity and growth in the industry, the figures for the exportation of similar products are even more significant. We submit figures for the years ending June 30, 1890, and June 30, 1900, respectively, including in the table some data for 1876, the year of the organization of our Society. To have predicted these results in the beginning of the quarter-century would have invited incredulity, but so also would predictions regarding the advances to be made in other lines of human industry. The figures are worthy of careful study.

Values of exports of domestic products of the chemical industries for the years ending June 30, 1876, June 30, 1890, and June 30, 1900, respectively:

	1876.	1890.	1900.
Bark and extracts for tanning	$223,276	$263,754	$376,742
Beeswax		17,927	91,913
Blacking	81,401	238,391	880,049
Candles	229,311	143,073	191,687
Celluloid		39,004	174,264
Acids	50,300	98,084	146,722
Ashes, pot and pearl	75,597	26,211	49,566
Copper, Sulphate of			2,120,745

For the year	1876	102,054,750
" " "	1890	174,803,105
" " "	1900	264,501,771

In the decennial period just closing the increase in the value of the exports of products of domestic manufacture was therefore about the same as during the preceding fourteen years, and during the quarter-century the growth has been 260 per cent. The growth has been persistent and steady, and indicates what may be expected in the immediate future as well as what is now the condition of development of our chemical industries. This latter condition becomes more manifest when we consider that the products exported constitute but a small proportion of the production, and we may in some degree at least anticipate the results which must be obtained in the pending census investigation.

As a further illustration of the growth of the chemical industries, we may call attention to the condition of the coke industry in the United States in 1880 and 1898 respectively, as illustrated in the following table:

	1880.	1898.
Establishments	186	342
Ovens { built	12,372	48,447
Ovens { building	1,159	1,048
Coal used, net tons	5,237,471	25,249,570
Coke produced, net tons	3,338,300	16,047,299
Total value of coke at ovens	$6,631,267	$25,586,699
Value of coke at ovens, per net ton	$1.99	$1.594
Yield of coal in coke, per cent	63.0	63.6

If we consider that in the recovery ovens, which are fast taking the place of the older and less rational types, this coal should yield 3.38 per cent. of tar, .34 per cent. its weight of ammonia and 8.17 per cent. of gas liquor, all of them bases of most important chemical industries, the figures are significant.

Equally interesting must be the information to be furnished regarding the capital represented in the chemical industries in this country. At the present time, we are able to judge of this to a minor extent from the reported capitalizations of the recently organized companies constituting combinations of preexisting companies. It is true that in these cases the capital represents in a very considerable measure what is known as good will, franchises, etc., but it nevertheless represents earning power and the the average market value corresponds very closely with par value. Taking only those organizations devoted to the chemical manufactures exclusive of the gas and metallurgical and explosive industries, we find that the capitalization as reported in the stock lists amounts to the enormous value of about $1,500,000,000, and this takes no account of many of the incorporated industries not specially reported, nor the industries not incorporated and yet active. It does not include the recently developed electrolytic industries, in which the cash capital actually invested, as we learn from competent authority, amounts to more than $1,500,000. The newly-established by-product coke industry is so rapidly developing and is absorbing capital with wonderful rapidity, while the comparatively new beet root sugar industry has already developed to such an extent as to involve capitalization of nearly $100,000,000 and to develop the establishment of manufacturing plants of magnitude beyond the imagination of foreign manufacturers in the same line a few years ago. Yet this is a general characteristic of the modern chemical industries of the United States, and it is interesting to note that much of the development has been effected empirically and by men comparatively little versed in the principles and laws of the science upon which they are based. The industries have had the aid of but few educated chemists. Happily this condition is rapidly changing. Rational

work is coming to be recognized and the demand for well-trained chemists is increasing. We cannot yet boast with the Germans that single works employ more than one hundred thoroughly educated chemists, yet inquiry shows that many of the important works have corps of chemists numbering from ten to fifty, while very many more have smaller numbers. The same inquiry affords some clue to the number of chemists actually at work in this country. If we compare the list of members of the American Chemical Society, we find that more than two-thirds are engaged in technical work. Furthermore, of the few chemists reported in the inquiry just referred to, scarcely one-third are members of the Society. A fair estimate based upon such data leads to the conclusion that more than five thousand chemists are actually at work in the United States and that eighty per cent. of these are connected with the industries. A study of the lists of the graduates of the educational institutions leads to similar conclusions. Fischer reported as the result of special inquiry made three years ago that in Germany four thousand graduate chemists were employed in the industries and about two hundred in teaching and special investigations.

So then we find that the chemical industries of the United States are growing with enormous rapidity; that they are being concentrated into fewer but larger works; that operations and reactions are being carried out with a magnitude which the earlier chemists would never have predicted; that new methods are being followed; new principles applied, greater accuracy of results demanded both as to quality and yield of the products; that the products now issue from the works in lots of tons at a time of a higher degree of purity and with a greater economy than were possible but a few years ago with lots of a few hundred pounds. For instance, the great sugar refineries each yield from one to two million pounds daily of a product, the purity of which may be considered absolute. The modern beet sugar works have in some cases capacity for treatment of from 1,000 to 3,000 tons of roots daily, and consequently the purification of almost an equal quantity of juice.

And if so great advance has been made during the closing quarter-century and even decade, what shall we say of the possibilities of the future? What is to be the magnitude of the chemical industries of the United States? What shall be the character of the products issuing from them? What will they require of the men who must direct and control them? That is to say, what will be the educational requirements of the American chemical industries of the almost immediate future? These questions are not new to our own country, and their importance has forced itself with powerful intensity upon those engaged in the chemical industries in the old world: it has been the subject of most earnest discussion, particularly in Germany and England, during the past five years at least. Nor has it been in all respects satisfactorily answered. Even within this closing month of the closing century the cable has flashed news of the complaint on the part of the leading statesmen of England that the training of technologists in that country is inadequate to the development necessary to meet foreign competition, and at almost the same time brings news of the inauguration of new institutions for technical education. And in Germany also, the home and starting point of many of the great industries, the demands upon the educational institutions for the better training of technologists are being pressed from every side. It is natural to believe that the time is not far distant when we too shall be called upon to make and meet similar demands. It may be pardonable therefore to discuss briefly what these requirements are likely to be.

First of all, experience shows that those who financially control the great industries fully appreciate the need of improvement in both processes and products are particularly apt in propounding hard questions in connection therewith, and always expect that these questions shall be answered quickly and with the utmost accuracy. Young men who early come to a realization of this fact and prepare themselves by broad and thorough education to meet it are those who will succeed in the industries and ultimately have a controlling influence in their management. And what is to be said here on this subject is directed as much to the students as to those who instruct, for it is not difficult to understand the restrictions placed upon teachers by the students themselves in the struggle to arrange work leading to the training, which many realize to be absolutely essential to meet the requirements of the near future.

For it is beyond question that the most thoroughly educated man is sure to best meet these requirements and become the leader in the industrial struggle of the near future. Dr. Duisberg, the director of the great color works at Elberfield, Germany, rightly fixed the standard when he said that 'above all a general comprehensive education is required. We must have in the industries persevering, energetic men with broad views.' And Dr. Chittenden was right when he said "give a young man a broad knowledge and a thorough conception of the principal laws of physics, mechanics, hydraulics, etc., and he will soon adjust himself to the environment of professional work and eventually rise to a plane far beyond that of the man whose training has been purely technical," and concluding his paper he says, "the rapid development of the sciences and their manifold industrial applications have opened up avenues for new ventures of great magnitude, and there is an increasing demand for young men of broad scientific knowledge and training. He who wishes for the fullest possible measure of success must prepare himself thoroughly for his life work and he can do this in no better way than by acquiring a broad and liberal education."

This important requisite to success could not be better described. Careful general training is conducive to the best thought and the best expression of the results of inquiry. And it is too frequently true that technical men are especially lacking in this particular. Too early specialization must tend to narrowness of view and therefore to limited influence. The general culture work of the preparatory schools, or of the colleges, will always be profitable, whether as preparatory to a specialty or an auxiliary to its prosecution. These principles will apply to all technologists, whether they are chemists or not.

But what shall be the character of the special training of the technical chemist? First of all, we must admit, that this must cover thoroughly and profoundly a study of the science of *chemistry*. Dr. Fittig declares: "Our problem is to study the science as such; to lead the student into the methods of strictly scientific investigation, to put him into position to solve pure scientific problems entirely independent of the question, whether he shall devote his powers to the services of the science itself or apply it to practical questions." He claims that many students take up the study without the scientific instinct. And Erlenmeyer says "a true scientific training should produce ability and susceptibility for all and every use. With a knowledge of the principles and laws of the science, their use becomes easy, they proceed independently." Foerster, discussing the needs of the electrochemists, says "but above all be particular to secure fundamental training in the entire field of chemistry, thus utilizing the principle insisted upon by Liebig, that the best

training for any specialty rests upon the broadest foundation in the whole of scientific chemistry." Dr. Duisberg says further: "in technical chemistry the sharp eye of the scientifically trained man is wanted in order to recognize the individual developments of the reactions in progress, which can be seen only through the accompanying indications." And Richard Meyer truthfully declared: "if our technologists did not properly appreciate the service rendered by men trained in the spirit of Liebig, chemical investigation would miss the stately crowd of auxiliary powers, without which the heights, from which we may now look proudly backward and hopefully forward, could never have been attained." And W. H. Perkin says that "technical education will be of small value unless it is carried out on a very broad and scientific basis."

These views of the leaders in the science of chemistry must find an echo in the mind of every man who has had experience in the industries. In no department of human activity is a thorough knowledge of the fundamental laws so needful, nor can the knowledge of any law be safely neglected if successful work is to prevail. For all the laws apply all the time and few cases will arise in which the more important can be avoided. To suppose that the industries can be carried on in the face of severe competition without such knowledge is to invite failure in every case. Empiricism may succeed in times of plenty, but adversity breeds rationalism and fosters the support it can bring. So then we may make no distinction between inorganic and organic chemistry, analytic and physical chemistry, for each one has its place in the world's work and no one can predict when any one of these branches will be called upon to render material aid.

But whatever may be the department of chemical study, the relation of the science to physics will be keenly felt and the dependence of each upon mathematics as the true foundation will become manifest. For this latter science is just as powerful an aid in the determination of the motions of the atom and molecule in matter as of those of the worlds and constellations in space. And if it cannot be neglected in astronomy, no more can it in chemistry and physics. Indeed, it illustrates the unity of all the sciences, even as it does the correlation of all the forces. Dr. Lorenz set forth the need of all chemists in this particular when he said: "Modern electro chemistry is an exact science and its principles and a knowledge of it rests upon a foundation of mathematics. It is in every way desirable that every electrochemist shall be trained in the higher mathematics and be thoroughly able to utilize both differential and integral calculus." He particularly recommends as a preparation therefor the 'Introduction to the Mathematical Treatment of the Sciences of Nernst and Schonflies' and says: "if the student have an intensive rather than extensive training in mathematics, he may be thrown into the sea of natural science and left to swim." So also Foerster discussing the character of the instruction in electrochemistry in the technical high school, while insisting upon 'thorough fundamental work in organic and inorganic chemistry, physics and physical chemistry' does not fail to include in his plan of work 'the principles of higher mathematics.' Dr. Koerner, discussing the 'Importance of Physical Chemistry to the Industries,' says: "It is most characteristic of it (physical chemistry) that it utilizes the most powerful of all natural aids to scientific investigation, the higher mathematics." And in the curricula of the technical high-schools in Germany we find almost without exception that in the course of chemistry, as well as in engineering, the higher mathematics is taken up and completed before the end of the first part of the year, if not

before the end of the first semester. It thus becomes the ground work of, and preparatory to, all the important work which in those great institutions must follow it.

And finally, the technical chemist of the near future must be trained in the principles and practises of engineering, trained to make and operate the mechanical means for carrying out effectively the chemical reactions of the industries in a large way. For, after all, these reactions differ only in degree from those of the research and preparation laboratories, and if in the latter the students must be trained in making and assembling the forms of apparatus for use in the various operations of pulverizing, separating, roasting and incineration, solution, precipitation, separation of solids and liquids, washing, drying, and care of precipitates and crystals, the production and control of heat, the transfer of solids and liquids, the production and application of vacuum, evaporation and distillation, the conditions of crystallization, etc., in the small way in the laboratories, he must be taught to apply all these and more, in the large way in the works. Indeed, the only difference between the two may be comprised in the terms micro-chemistry and macro-chemistry; chemistry and the operations belonging to chemistry, carried on in a small way with limited or small quantities or volumes; handling solids and liquids in quantities of a few grams or a few cubic centimeters, or liters, on the one hand, or of tons of solids and thousands of gallons of liquid on the other. How, for instance, would the chemist untrained in the principles of engineering proceed in handling materials in quantities involving several tons of solid matters and 30,000 to 50,000 gallons of liquid in a single charge?—a requirement not uncommon in the modern industries and sure to be more common in the future industry. In his day, perhaps, the great Liebig was right and Wöhler was right, and Fittig not far wrong, when they maintained that with a thorough knowledge of the principles and laws of chemistry, all else in the industry involving their application would be easy. It is possible that the genius of the young operator would come to his aid and enable him ultimately to devise means to meet his ends, but time and labor must be saved by training in the methods, whereby such means may be established and a knowledge of means already at hand acquired. The authoress of a late popular work of fiction was right when she said, 'untrained genius is a terrible waste of power,' and though it may not be as applicable here as in an earlier paragraph, she was also right when she said in the same connection, "So many persons think that if they have a spark of genius, they can do without culture; while really it is because they have a spark of genius that they ought to be and are worthy to be cultivated to the highest point." And this applies to the chemists who must operate in a large way and with large masses of matter, either solid or liquid.

In a discussion of this subject in England, where perhaps more than elsewhere in the world the need of engineering capacity on the part of chemists has been most keenly felt, and where, on the other hand, engineering capacity, embodied in such men as Mond, Bell, Muspratt, Weldon, Perkin and Chance, has brought forth such splendid results. Ivan Levinstein, himself a leader in the industry, said: "It must also be palpable that a chemist intended for industrial work, who, along with sound training in chemistry, has also acquired a fair knowledge of chemical engineering, must be better fitted for his work than the man who is only practically acquainted with the handling of china basins, phials or a Liebig's condenser." And in the same discussion Watson Smith endorsed "what had been said as to the importance of teaching

the scientific principles involved in the special construction of apparatus and plant for chemical processes on a large scale."

Dr. Ost, whose connection with both the industries and teaching has been so intimate, says: "Liebig, who had for long years taught technical chemistry in Giessen and, as none other, had promoted the applications of chemistry, could say in 1840 'I know many (those trained in pure science only) who now stand at the head of soda, sulphuric acid, sugar and cyanide works, dyeing and other industries, and without ever having had previously to do with them, were completely entrusted with works processes within the first half-hour, and in the next brought forth a number of most important improvements.' Sixty years ago, this judgment characteristic of the time, this enthusiastic declaration of Liebig, would constitute a dogma, but it is no longer tenable. The chemist graduated from the technical high school is no longer in position to begin his factory experience with introduction of improvements." This, Ost says, is because of the better and more perfect organization of modern works. And Dr. Lorenz of the Zurich Polytechnicum says: "The electrochemist should not be graduated until he has been taught how to use modern methods in very large apparatus. We find in electrochemistry wide difference between the theory and the facts. In the laboratory current yield and greatest economy of electrical energy are often the principal consideration, but in technology corrosion of electrodes or diaphragms is much more expensive than any variation of energy." What an important illustration of a special study of materials of engineering in the preparation for the chemical industry. And what a sensation of sympathy this must arouse in all those who have had to do with the handling of corrosive materials in the very large quantities and volumes, which modern methods involve. How often it happens that success of an important operation is delayed and even made impracticable because of want of knowledge of suitable resistant material for construction of containing vessels or apparatus.

Probably the most important contribution to this subject is that of Mr. Beilby. In his address he says: "I have rarely seen the chemistry of a process lagging behind the engineering; most frequently it is the other way. The chemical reactions involved in the ammonia soda process are simple and easily understood, but it required the genius and practical skill of men like Solvay and Mond to devise apparatus which could establish the manufacture on its present secure basis. What are the elements of which the skill is made up? The scientific basis must be a thorough knowledge of the principles of chemistry, physics, dynamics and mechanics, and added to this there must be a practical acquaintance with the materials of construction and the methods by which they are worked into structures. The designing and construction of apparatus for chemical works is a distinct branch of applied science. It is in this that special skill is required, for works operations are not simply laboratory operations.

"The ideal chemical engineer should be in thorough sympathy with the modes of thought and with the methods of working of both the chemist and the engineer. Just as the professor of engineering teaches how to apply the law of statics, dynamics and kinematics to the design of structures or machines, so should the professor of chemical engineering trace the applications of the laws of chemistry and physics and dynamics in the problems which occur in designing chemical apparatus for works. I am quite satisfied that in the present state of popular opinion the position and work of the technical chemist will not be properly recognized, unless he can associate himself, by his training and practice, with the engineering

side of his calling." Professor Meldola says: "The sooner a chemist is made to realize the enormous practical difference between a laboratory and a factory process, the better it will be for him."

Professor J. A. Reynolds, Director of the Municipal Technical Schools of Manchester, England, says: "English chemists are not engineers and English engineers are not chemists, and hence the enormous difficulty which arises in the endeavor to bring to successful commercial results the fruits of laboratory research." While Mr. David Howard considers that the "influence of mass action, the question of so many pounds of coal per horse power hour and other like things, cannot be dealt with on a small scale, but are all important on a larger scale. We want chemical engineers who can make new roads in chemistry as mechanical engineers do in railways."

It is also important to consider the course of study proposed by Mr. Beilby in his paper for prospective industrial chemists. His large experience in the chemical industry gives him power to speak with authority, and young men who look forward to a successful career in the industry will do well to give it most careful consideration. And even more important, perhaps, are the courses of instruction carried out in the West of Scotland Technical College and in the Municipal Technical School in Manchester, England, and published in the *Journal of the Society of Chemical Industry* during 1899. Students who have had the advantage of these courses must be better fitted than those who have not been similarly favored. Yet we must believe that the courses laid out in the technical high-schools of Germany, and, we are proud to say, in some of the schools of technology in our own country, are in some respects better. A combination of the two classes of course might be made with profit to both the classes of institutions. It is important that the works chemist should be trained in the construction of the special forms of apparatus he needs to use, but they should be accompanied or preceded by the principles and practise of mechanical engineering. The most practical courses, perhaps, are those laid down in many of our own educational institutions for instruction in mining engineering and metallurgy, in which chemistry of the operations is considered in connection with the mechanical details of its applications, and we have advised students desiring to prepare for the chemical industries to pursue these courses in the best institutions first, and to follow them with a year or more of exclusive study of chemistry both pure and applied. If it were possible to add to the courses of chemistry as much of engineering, civil, mechanical and architectural, as is found in some of the metallurgical courses, the ideal would be nearly met. But we can fully sympathize with those teachers who find the time available too limited for such a combination, and appreciate the fact that either the student must come to the professional school with better preliminary training in the preparatory subjects, or the course must be extended beyond the usually provided four years' work. In any case, if the course of engineering could be carried side by side and simultaneously with the course of chemistry, the needs of the prospective technical chemist would be most fully met and the requirements of the future chemical industry most nearly fulfilled. In some of our institutions in which all studies are practically optional, such a course might be arranged and profitably followed, and notwithstanding the longer time which might be involved in its completion, the graduate from it would issue with brighter and better prospects of success in his profession than one less broadly trained. And in the selection of the subjects for such a course, the

plans of study laid down in the technical high-schools of Germany, in the technical schools of England and of our own country, may be profitably followed.

In 1897, we expressed the view which seems thoroughly applicable now and which will perhaps bear repetition here. We said: "It seems, therefore, that the demand of the present time and of the immediate future can be met only by broadly educated men: by men who have been trained, not only in chemistry itself, but in the great principles of physics as well. A good technical chemist must be first of all a thoroughly educated chemist. After that, to attain the highest success in this country, he must be educated in the principles of engineering; the production and applications of heat; the production and applications of electricity; the transmission of power, the movement of liquids; in general, the means whereby the reactions of chemistry may be carried out in a large way We need, therefore, chemical engineers, and these in the nature of the requirements must be broadly and thoroughly educated men. While they must be trained in the work of the research laboratories, which are being organized in connection with many of the great industries, they must likewise be prepared to put into practical operation in a large way the results of the researches they have been called upon to make."

These truths have not changed and if these conditions of education and training are fully met, the progress of our chemical industries must be greatly augmented, the science must, by reaction, be actively advanced and following the experience of our German confrères in the words of Meyer, we may look hopefully forward, and in the near future proudly backward, to accomplishments greater than the world has ever known. WM. MCMURTRIE.

NEW YORK.

MAN'S PLACE IN NATURE.*

IN the opening paragraphs of his most memorable contribution to knowledge ('Man's Place in Nature,' 1863), Huxley made mention of certain similarities between the activities of anthropoids and those of men; and, while the burden of the work was devoted to structural homologies, the initial keynote was retouched here and there throughout the discussion. Huxley's classic contribution to anthropology needs no encomium; it was a pioneer's mile-mark of progress, erected under difficulties; and it suffices that all later travelers have found it in the direct way of experiential truth. Yet it is worth while, now and then, to take stock of advances subsequent to, and largely consequent on, the Huxleian declaration.

Since Huxley's pioneer work, a host of investigators have carried forward the study of structural homologies connecting the genus *Homo* with lower genera and orders; and to-day the physical similarities are among the commonplaces of knowledge, whatsoever the background of philosophical opinion concerning cause and sequence. During the last decade or two the investigators themselves, with scarce an exception, have gone one step further, and now include sequence of development from lower to higher forms as among the commonplaces of opinion, whatsoever the background of metaphysical notion as to cause. There the strictly biologic aspect of the question as to man's place in nature may safely be considered to rest; there has been little advance in opinion beyond that of the pioneer in 1863; but the data have been multiplied, and the knowledge and opinion have been diffused widely.

Since Huxley's epoch-marking memoir

*Address of the retiring President of the Anthropological Society of Washington, delivered before the Washington Academy of Sciences and Affiliated Societies, February 26, 1901.

was first published, occasional contributions have been made to knowledge of the activities displayed by various sub-human animals, and during the last quarter of the nineteenth century a science (which has been called the New Ethnology) has been organized to deal with the activities of mankind; yet singularly little has been done in the way of tracing activital homologies between the genus *Homo* and lower genera. It is indeed conventional for sociologists, and customary for comprehensive writers on anthropology, to instance the social habits of mammals and birds, and even of insects and infusoria, as analogous to human society; one naturalist has gone so far as to study various mammals and birds in their activital aspects, thereby opening a most attractive field in science as well as in literature; but investigators have not turned seriously toward the habitual activities displayed by the anthropoids—still less have comparative studies been made of the activities normal to both the higher quadrumana and the lower races of mankind, albeit this is perhaps the most inviting field now open to research. Thus far this line of inquiry grovels in the stage of travelers' tales: the gorilla-hunter tells how the family sire sleeps at the foot of a tree in which mother and young are nested; the naturalist in Liberia incidentally describes the use by monkeys of stick and stone implements, while the Bornean tourist tells of the simian servant who prefers the society of human masters to that of his kin and discriminates among the garments he is permitted to wear; but there is a woeful dearth of critical observation and a lamentable lack of judicious generalization pertaining to this promising meeting-ground of zoology and anthropology. So this aspect, too, of the great question concerning man's place in nature remains nearly as it was left by Huxley; the data are more abundant, and opinion has been both clarified and diffused; yet definite homologies remain practically unfound, if not unsought, and the scattered facts have thrown little light on cause, less on sequence.

Since Huxley's prime, the New Ethnology has arisen; and it has opened a vista of facts and relations which apparently escaped the keen vision of the pioneer in 1863—the vista embracing thought, with all the other psychic factors pertaining to the activities, sub-human as well as human. This vista is perhaps the broadest and most attractive ever opened by science: When Galileo descried the harmonious paths of the planets in a sun-centered system, he raised the minds of men to a new plane; when Newton grasped the idea of gravitation, he gave human thought a new hold on nature; when Darwin discerned the lines of specific development, he wrought a revolution in the world of intellect; but when students still living scanned the lines of activital development and realized that thought itself is bred by the very activities over which it comes later to hold dominion, they opened a new intellectual world—a world at once so novel and so commanding that some of the students themselves are fain to sit at the gate and view the prospect as fleeting phantasm rather than veritable reality. Nor is their hesitation either unprecedented or unpardonable: When the biologists of only one long generation ago unrolled the scroll picturing the origin and perpetuation of species through natural interactions, their interpretation seemed too simple to be true; when the anthropologists of the present generation unrolled a similar scroll picturing the origin of activities (arts, industries, laws, languages, doctrines) through natural interactions and self-developed interrelations—and in this way alone,—their interpretation in turn seemed too simple to be true; and when the anthropologists of the old century's end (and

of this Society) unroll a scroll picturing the origin and development of thought itself through the long chain of interactions between the thinking organism and external nature—and in this way alone,—they foresee that their interpretation must seem too simple to be true—though they find comfort in the teachings of experience that in the long run simple explanations are preferred, that simple doctrines at last prevail, indeed that the progress of knowledge is best measured by its own simplification. But even after full allowance for hesitation and doubt, it must still be said that the opening of the post-Huxleian vista has had much effect; it has widened the view of nature to include the psychical as well as the physical aspects of organisms; it has correspondingly narrowed the range of extra-natural explanations of phenomena; and, specifically, it has revealed a new class of homologies among the races of men and between these and sub-human organisms. So the homologies recognized to-day as defining man's place in nature are of three classes: (1) structural, as wrought out by Huxley; (2) activital, as suggested by Huxley and wrought out by Powell; and (3) mental, or psychic. Expressed otherwise, man's place in nature is now defined, first by what mankind and their kindred *are*, second by what they *do*, and third by what they *think*. And the chief progress of the post-Huxleian epoch, albeit practically confined to *Homo sapiens* in various grades of development, has followed the lines of psychic homologies.

It is just to say that the foundation for modern knowledge of psychic homologies was laid by Tylor in his 'Primitive Culture' (1871), and especially in the seven notable chapters on animism elaborated in successive editions; for he showed that a certain type of philosophy is of world-wide extent, and is, or has been, shared by every race, every known people, whatsoever their diversities of color or condition. This foundation was gradually raised into a definite platform partly by Tylor in later publications, partly by Powell in brief memoirs on 'The Mythology of the North American Indians' (1879) and 'Activital Similarities' (1881), in which it was shown that the interactions between distinct peoples and similar environments frequently produce similar activities, howsoever diverse the peoples themselves; and important additions to the platform were made by Brinton in various contributions summarized in his 'Religions of Primitive Peoples' (1897), in which he showed that the human mind, even in its more complex operations, reflects environment with striking fidelity. True (as recently shown by Boas*), the products of interaction between peoples and environment are in some measure inconsistent and may even at first sight seem contradictory; but, as pointed out on a previous occasion,† the incongruities shrink or disappear when the comparisons are confined to peoples in corresponding degrees of cultural development.

The modern platform for the study of psychic homologies may be defined briefly in terms of a few generalizations, which seem to be consistent with the sum of knowledge concerning the psychic attributes of both human and sub-human organisms, viz.: (1) the mentality of animals is instinctive rather (or more) than ratiocinative, and for each species responds practically alike to like stimuli; (2) the savage mind is shaped largely by instinct, and responds nearly alike to like stimuli; (3) all barbaric minds are measurably similar in their responses to environmental stimuli; (4) civilized minds rise well above instinct, and

* 'The Mind of Primitive Man,' SCIENCE, Vol. XIII., 1901, pp. 281–289.

† 'Cardinal Principles of Science,' *Proceedings of the Washington Academy of Science*, Vol. II., 1900, p. 11.

work in fairly similar ways under like stimuli; and (5) enlightened minds are essentially ratiocinative, largely independent of instinct, and less uniform in their responses to external stimuli than those of lower culture. The several generalizations are mutually and significantly harmonious; they combine to outline a course of development beginning in the animal realm with organisms adapted to environment through physiologic processes, and ending in that realm of enlightened humanity in which mind molds environment through nature-conquest;* and they measure the gradual mergence of bestial instinct in the brightening intellect of progressive humanity. To, or at least toward, this platform those working anthropologists concerned with the broader aspects of the science have been pressed by accumulating observations and generalizations; yet the platform owes much of its character and most of its strength to the concurrent development of a scientific psychology at the hands of a notable group of experimentalists in psychic phenomena. The several generalizations embodied in the platform have already been summarized as the latest and most comprehensive among the principles of science, *i. e.*, the responsivity of mind;† and by aid of this principle, psychic homologies may be traced between higher culture-grades and lower, and from people to people and tribe to tribe, down to the plane of lowest savagery—where the lines cease for lack of data, leaving the lowly mind in a state even more suggestively akin to that of the sub-human organism than is the lowest human skeleton to that of the highest anthropoids.

*Cf. 'The Seri Indians,' *Seventeenth Annual Report, Bureau of American Ethnology*, 1898, p. 269.

† "The cardinal principles of science may be reckoned as five: the indestructibility of matter, the contribution chiefly of Chemistry; the persistence of motion, the gift mainly of physics; the development of species, the offering of the biotic sciences; the uniformity of nature, the guerdon of geology and the older sciences; and the responsivity of mind, the joint gift of several sciences, though put in final form by anthropology." *Proceedings of the Washington Academy of Sciences*, Vol. II., 1900, pp. 11–12.

Especially within the last decade of the old century, anthropologists have come to recognize a course of development of the esthetic arts—a sort of natural history of esthetics, arising in symbolism, running through conventionism, and maturing in a degree of refined realism found satisfying by civilized and enlightened peoples. Now a significant feature of this development is found in the fact that the initial symbolism is zoic or animistic, putatively if not patently. The esthetic hunger of primitive artists is sated by the carving of totems on reefs or rocks, by the molding of animal effigies, perhaps by the delineation and painting of zoic pictographs; as the artists rise in the scale of culture the zoic designs are partly conventionized (eventually passing into arbitrary alphabets), partly perpetuated in more realistic forms still conceived as fraught with mystical meaning, like the asp of Egyptian sculpture, the dragon of oriental painting, the curiously vestigial unicorn of a modern nation's coat-of-arms, and even the eagles of other national insignia. So, also, when primal man first yields to the charm of music, his songs and accompaniments mimic the rhythmic footfalls of feared or venerated animals, the rustling sounds of animal movements, the inchoate melody of animal voices; when he enters the demesne of drama, his characters are beasts or uncanny monsters tricked out in zoic trappings; and it is only after long stages of development that anthropomorphic motives are introduced, and that the music and drama rise to the plane of realistic representation. In some cases, if not commonly, the germ of esthetic development quickens in painting of face or body, to grow into tattooing; in simplest form the painted devices may serve as

beacon-marks for the identification of kindred (like the face-marks of various animals), as among Seri matrons,* or may symbolize fearsome animals, as among Sioux warriors; but in every well-known case the motive is symbolic expression of zoic attributes. From these germinal efforts of esthetic faculty to that modern stage of art in which the noblest realism and the highest idealism are wedded, the way is long; but every step is marked by the dropping of zoic motives and the substitution of motives springing from human attributes and aspirations.

Within a few years working anthropologists have come to recognize more or less clearly a natural history of industries, comparable with that of arts—a course of development also arising in symbolism, running through instinct-guided conventionism, and maturing in that sublimest product of mentality, invention. It has long been known that barbaric artisans seek omens among birds, borrow lore from beasts, and run to zoic motives in decoration;† it has long been known, too, that savage huntsmen not only imitate the movements of feral animals in the chase and seek to incite their weapons and strengthen their arms by zoic trophies, but even mimic the carnivores' blood-craze in berserker rage at times of battle; and more recently it has been noted that the most primitive implements are of tooth, claw, shell and bone, selected and used as emblems of zoic power. In a typical tribe—the Seri, most primitive of known Amerinds—the pristine implement is a sea-lion tooth, differentiated into arrow, harpoon and fire-stick; the teeth themselves are classed as stones, and natural pebbles are used for tools emblematic of the zoic organs, while the methods of chase and warfare still mimic the habits of local beasts. The lines of human progress from primal savagery to enlightenment may be traced in terms of development of each or all of the great groups of activities; and while all the tracings conform so closely as to inspire confidence in each, no outline is more definite than that represented by the stages of industrial progress—stages best defined in terms of the mind-led activities of which artifacts are normal products. These stages (beginning with that typified by the Seri) are: (1) Zoömimic, in which bestial organs are used as arrows and other implements, to which magical powers are imputed by dominating zootheistic faith; (2) Protolithic, in which naturally formed stones are used for cleavers and other implements, under the sway of mystical faith modified by experience of mechanical chance; (3) Technolithic, in which design-shaped stones are used for knives and other implements in ways revealing the germ of invention; and (4) Metallurgic, in which ores are smelted and used for tools under the influence of invention.* Whether the progress be traced through these stages or otherwise, the way from the simple industries of the prime to the elaborate devices of modernity is long, very long; yet a full half of the steps are marked by the dropping of zoic motives and the substitution of motives expressing man's growing consciousness of power in nature-conquest.

Since Tylor traced primitive culture, and especially since Morgan wrote on 'Ancient Society' (1877), it has been recognized that all known primitive peoples are banded in consanguineal groups, while advanced peoples are bound in larger groups by laws defining proprietary and personal rights;

* The somatic and telic functions of face-painting are discussed in 'The Seri Indians,' op. cit., pp. 167 et sec.

† Even the faith-guided anti-zoic motive of arabesque decoration attests the force of the zoic tendency and the effect required to divert it.

* The stages and transitional sub-stages are set forth in greater detail in 'The Seri Indians,' op. cit., pp. 249–254.

and during the last decade or two working anthropologists have come to recognize the course of development of social organization in its several stages, *i. e.*, the natural history of law. Now it is significant that the most primitive social bond (found alike in America, Africa, Australia and parts of Asia) is that fixed by the ocular blood kinship of maternity, and that the next great stage is defined by paternal relationship; for in both stages the lines seem to be homologous with the instinctive habits of sub-human species, while the earlier the more closely approaches the low plane of brute knowledge—so far as this can be inferred from brute conduct. The researches among the aborigines of America have thrown strong light on the lowly laws of primitive peoples; for it has been ascertained that both savage clans and barbaric gentes are bound not merely by community of blood, but welded into homogeneous units by community of faith in zoic tutelaries—faith so profound, so blent with fear and hope, so impressed by recurrent ceremony from birth to maturity and thence to old age and death, as to dominate every thought and regulate every action. The Amerind tribesmen are grouped by totems (or tutelaries) of Wolf, Badger, Bear, Fox, Deer, Coyote, Eagle, Bluejay, etc.; they call themselves wolves, or badgers, or Bears, or Eagles, and glory in the strength and magical prestige believed to be brought them by their genii; most of them recite traditions of descent from the tutelary animals, or else from fantastic monsters invested with their attributes; and every adequately studied tribe has been found to possess a traditional genesis or sacred cosmogony in which the tutelaries, and perhaps other beasts, are glorified if not deified. The exoteric bond of clan or gens is blood-kinship; but the union is reinforced by an incomparably stronger esoteric bond of animistic belief. The way from beast-clanship to free citizenship is long—so long as to afford the most striking measure of human progress; yet every step of the way is marked by the elimination of zoic concepts and by the substitution of those concepts of higher humanity forced on the genus *Homo* through the ceaseless strife for nature-conquest.

During some decades past, students of aboriginal tongues have been impressed by the failure of primitive folk to discriminate clearly between men and animals in their every-day speech; and this lowly habit forms one of the phenomena which have served (as recently shown by Powell*) as a guide to the natural history of languages. Many Amerind tribes denote themselves by a term connecting animals, either in general or of a particular class, and when pressed to specify are compelled to employ an affix or adjective to distinguish the human kind (often considered inferior) from the rest; some, like the Papago, trace human genealogy through only a few generations, forward or backward, and conceive the lines as beginning and ending in an undifferentiated magma of zoic life designated by a single term; while some groups have progressed so far in the way of human superiority as to dignify themselves by the expressions 'Real Men,' 'True Men,' etc., in contradistinction from alien tribes and other contemptible creatures. The scroll picturing the development of language is expanded about midlength by the addition of the scriptorial branch, representing the growth of graphic expression: and it is quite in accord with the growth-lines of oral expression to find that the earliest essays in ideography are pictures of zoic objects, or objects to which zoic attributes were manifestly imputed. Most of the primal features of modern alphabets have been conventionized beyond recognition, but the hieroglyphs

* 'Philology, or the Science of Activities designed for Expression,' *The American Anthropologist*, Vol. II., 1900, pp. 603–637.

of Mexico and Egypt and the ideographs of China are among the clearer vestiges of primitive standards, while the fancy-wrought constellations of the celestial sphere —birth-mates of pre-Cadmean characters remaining unchanged by reason of remoteness from practical affairs—still conserve the graphic zoolatry in which writing began. The way from lowly language linking men and beasts in word and sign to a discrete graphic vocabulary is long; yet the earlier steps were unquestionably marked by the dropping of instincts shared by brutes and the substitution of humanitarian concepts impressed by ever-widening human associations.

Since Tyler taught the world-wide range of animism in 1871, anthropologists have grouped the myths and faiths of mankind in a series of stages outlining a course of development—a natural history of doctrine —coming up through a slavish and despairing hylozoism, and ascending thence through higher zootheism and broadening worship of nature-powers on successive planes each brighter and more humane than the last. The zoic factors in primitive arts, industries, laws and languages were manifestly made potent in the olden time, as they are to-day among lowly folk, alike by overweening faith and ever-present custom; they were, and still are, kept alive not only by recurrent ceremony and daily taboo and hourly precept, but by tireless study of animal contemporaries whose habits huntsmen must know under pain of hunger; so that much (perhaps most) of the sentient feeling of primal man must have been—as it is to-day among his survivors—of animal contemporaries. In savage life men and their animal associates are compelled to consecrate their best efforts to a study of each other; in affairs of feeling and faith as in matters of immediate utility, the association engenders habits of body maturing in instincts eventually ripening into action-shaping habits of mind; and the strongest mentality is naturally the more deeply influenced—until continued experience of superior faculty awakens consciousness of superior power, stirs the sleeping giant of self-confidence and rends the shackles of zoophobia forever.

> Lo, the poor Indian! whose untutored mind
> Sees *Beasts* in clouds, or hears *them* in the wind:

so a modern Pope would write of the American natives; and so, too, he might write of any and all other aborigines made known through the researches of the last half-century. The upward way from primal beast-faith through concurrent fetichism and shamanism, and thence through mysticism and all manner of occultism, is long and need not now be traced; it suffices that all of the earlier and many of the later steps were marked by the dropping of zoic motives or vestiges, and the substitution of ever nobler motives and imageries.

When the scrolls picturing activital development are brought together—when the natural history of doctrines is outlined over those of languages, laws, industries and arts—the leading lines are found consistent in every essential feature; and all are seen to rise from a mentality both reflecting and approaching that of lower animals (though just how closely may not be measured until the sub-human mind is better understood) toward the higher human plane revealed in science and statecraft. The savage Seri—lowest of American tribesmen —is loathed by Caucasian neighbors as an uncanny beast, and it is a revelation to find that he reciprocates the loathing and glories in the contumely, feeling that it allies him the more closely with venerated consociates like puma and shark, and divides him the more widely from the hated white creatures of unnatural ways; and the sentiment of the Seri is measurably common to all

aborigines of strong individuality. The impressive fact, learned alike through observation of a typical tribe and through analysis of the mental operations of primitive peoples in general, is that the savage stands strikingly close to sub-human species in every aspect of mentality as well as in bodily habits and bodily structures.

Since Huxley's prime the chief advances in anthropology have related to what men *do* and what men *think;* and the progress has been such as to indicate with fairly satisfactory clearness the natural history of human thinking as well as that of human doing. Thereby man's place in nature may be defined more trenchantly than was possible in 1871: (1) As shown by Huxley, the structure of *Homo sapiens* is homologous with that of lower orders, while the morphologic differences between highest anthropoids and lowest men are less than those separating lowest men from highest men; (2) As suggested by Huxley and established by later researches, the activities of *Homo sapiens* are homologous with those of the anthropoids, while the activital range between club-using gorilla and tooth-using savage is far narrower than that separating the zoomimic savage from the engine-using inventor; (3) As shown by the latest researches, the mental workings of *Homo sapiens* are homologous with those of lower animals, while the range from the instinct and budding reason of higher animals to the thinking of lowest man would seem far less than that separating the beast-fearing savage from the scientist or statesman. The resemblances and differences in doing and thinking may not yet be measured in definite units, as are cranial capacities and facial angles (though the recent progress in experimental psychology gives promise of quantitative determinations of general sort at no distant day); yet the relations are hardly less clear and tangible than those customarily measured in inches and ounces and degrees.

So, in the light of the latest researches, man must be placed wholly within the domain of nature, yet above all other organisms at heights varying widely with that highest product and expression of nature, mental power.

W J McGee.

THOMAS BENTON BROOKS.

Thomas Benton Brooks was born June 15, 1836, at Monroe, N. Y. He died November 22, 1900, at his home near Newburg, only a few miles from his birthplace, but during the sixty-four years of his life he had gone far, not only to distant countries but also to fields of experience and thought remote from his early environment. Born to the associations and inheritance of a small farm in a country district, he made his way to a prominent position in engineering and geology by his energy, ability and originality.

His early training and also his later education embodied more practise than theory. The district school, two years (1856–58) at the School of Engineering, Union College and a single course of lectures on geology under Lesley at the University of Pennsylvania (1858–59) cover his formal education, but he seized with eager purpose opportunities to learn in the school of practise. By observation of field methods he fitted himself to pass from axeman to rodman, levelman, transit man and topographer, first on surveys for the Erie Railroad and later on the newly initiated topographical and geological surveys of New Jersey in 1853. In this latter connection he served as axeman to an Austrian who employed a then little-known instrument, a plane table, and Brooks by watching him became so proficient in its use that he succeeded his chief. He was then seventeen. Subsequently, while a student at Union College, he made

extensive surveys in the forested mountainous region west of the Hudson, the Highlands. To this experience he added that of service during one winter with a Coast Survey party in the Gulf of Mexico.

The outbreak of the Civil War found him, at the age of twenty-five, established as a trusted leader among his associates. Enlisting as a private, he was followed by a number of those who had known him as a surveyor, and he was mustered into service as 1st Lieutenant, Company A, New York Volunteer Engineers, September, 1861. He served until the fall of 1864, when he resigned at the request of his parents after the death of his brother, Lieut. J. H. Brooks, in the trenches before Petersburg.

Major Brooks, as he was generally called, although he reached the rank of Brevet Colonel, won conspicuous recognition as a military engineer at the sieges of Fort Pulaski and Fort Wagner. His industry was indefatigable, his engineering talent manifest, his courage, devotion and self-sacrifice unfailing.

After a year with the New Jersey Geological Survey, in August, 1865, Major Brooks accepted a position as vice-president and general manager of the Iron Cliff Mine near Negaunee, in the Marquette iron district, Lake Superior. Therewith his more important work in geologic research may be said to have begun. The geology of the Lake Superior Basin had previously been scanned by Foster, Whitney, Houghton, Logan, Agassiz and others, and the Laurentian, Huronian and Silurian systems had been vaguely distinguished; but the pressing problems of the geology of the iron ores and related formations remained untouched. The difficulties of investigation in that district are even now very great. Forest, windfall and underbrush make the physical labor of exploration severe; drift mantles wide areas, and the relations of the folded, refolded, squeezed and metamorphosed formations are extraordinarily intricate. Settlement of the wilderness, extensive prospecting and mining operations and the development of modern petrographical methods have made a solution of these relations possible, but when Brooks faced them the difficulties were unequaled, the means and methods sadly inadequate. Nevertheless, he attacked them with characteristic energy and originality. He invented methods, he provided means, he spent himself, and he achieved the greatest measure of success then possible. In general geology he contributed important data and conclusions on the great geologic systems and the unconformities which separate them. In theoretical geology he first suggested that secondary deposition might be the genetic condition of the iron ore bodies. But it was in applied geology that he made his chief contribution, one in which he found most satisfaction, and one for which not only Michigan is his debtor, but also the people of the United States. Our country's iron and steel industry, our machine shops, our railway systems, and all the wonderful material conquest of the continent have been greatly promoted by exploitation of Lake Superior iron ores. Brooks took hold of that exploitation in its beginning, and he had a leading part in its development. Simple methods were needed of surveying in the unbroken forest amid widely varying magnetic attractions. Brooks devised the dial compass and taught men to pace distances in the most tangled underbrush. Magnetic surveys were necessary as a means of prospecting. Brooks adapted the dip needle to the capacity and purposes of the prospector. Men wanted practical advice based on scientific principles. Brooks harnessed his practise and his science together, and thus became the most reliable mining engineer, as well as the most useful geologist, in the region.

As the chief authority on the iron-bearing formations of the Upper Peninsula, Brooks was asked in 1869 to take charge of the Economic State Geological Survey of that district, and he accepted on condition that he should be allowed to secure all the private aid possible. The necessity for this provision is apparent when it is understood that during four years the State paid toward the work but $9,000, while he spent $2,000 of his own means and received no pay himself. The results of his work are embodied in Volumes II. and III. of the Michigan State Geological Survey. His reports are direct in style, simple in treatment and extremely practical in substance. They are models of excellence as economic geologic reports. The most original chapters, and those which still possess most practical value, relate to the principles of mine management and of magnetic observations in prospecting for iron ores. For many years the chapters on geology were standards of reference, and they have been replaced only by most elaborate studies, based largely on Brooks' work and carried out with the most refined methods of modern geology. Says Van Hise, Brooks' successor: "Notwithstanding the immense advantage which it has been to have Brooks' work as a foundation, it has taken many years of labor fairly to complete the structural story to which Brooks contributed important chapters. Only those who have labored in the Lake Superior region and who understand its peculiar difficulties can give Brooks credit for the remarkable work he did. His geological work is my ideal of what should be done in a new region of complex geology."

In 1873 Major Brooks' health gave out under the stress of overwork to which he drove himself. He sought relief abroad, and resided in London and Dresden while completing his State reports. He became a Fellow of the Geological Society of London and Corresponding member of the Geological Society of Edinburgh. Returned to this country in 1876, he resided at Monroe and at Newburg, N. Y., and after 1883, during the winters, at Bainbridge, Ga., living the life of a country gentleman and farmer. His interest in science and engineering practice never abated, and he was always ready with wise counsel, even though strength failed him for action.

Major Brooks was characterized by intense energy, which exhausted his physique before he reached middle age; by originality, which combined with common sense made him a most efficient man of affairs; by keen powers of observation and deduction, which he applied untiringly to scientific research; by geniality and affection, generosity, truthfulness and loyalty to principle, which made him beloved and stamped him as a man whose memory will be honored and revered.

BAILEY WILLIS.

U. S. GEOLOGICAL SURVEY.

SCIENTIFIC BOOKS.

THE APPRECIATION OF NON-EUCLIDEAN GEOMETRY.

Histoire des Mathématiques. Par JACQUES BOYER. Paris, Carré et Naud. 1900. 8vo. Pp. xi + 260. Price, 5 francs.

Geometry: Ancient and Modern. By Professor EDWIN S. CRAWLEY. *Popular Science Monthly* (January). 1901. Pp. 257–266.

Non-Euclidean Geometry. By Professor HENRY PARKER MANNING. Boston, Ginn and Company. 1901. 8vo. Pp. vi + 95.

The last section of Boyer's attractive book is headed 'Géométrie Euclidienne et Géométries non-Euclidiennes.' He says, p. 240, "The last quarter of the nineteenth century witnessed the building up of interesting theories." The next page continues: "But beyond contradiction the most original researches of this period pertain to the non-Euclidean geometries, and it is by them that we will terminate this incomplete exposition of contemporary science." The brief account which follows (less than five

pages) is certainly stimulating, and is adorned by a full-page portrait of Lobachevski, taken from that given in the Kazan edition of his collected works.

But there is extant another picture of Lobachevski far more impressive, showing him in the plenitude of his powers, which I first saw at Kazan, a daguerreotype from the life, a copy from which you may see as the frontispiece of Engel's monumental 'Nikolaj Iwanowitsch Lobatschefskij.'

As for Boyer's account of what he rates so high, it begins as follows: "From long ago it has been sought to demonstrate the famous axiom laid down twenty centuries ago by Euclid, to wit: through a point only one parallel to a given straight can be drawn."

This of course is not Euclid's postulatum, but rather a paraphrase of what is called (even by Cajori) Playfair's axiom, though Playfair explicitly credits it to Ludlam, namely: "That two straight lines which cut one another can not be both parallel to the same straight line." Boyer continues: "These attempts remained unfruitful. However, at the end of the eighteenth century, an Italian Jesuit, Saccheri, wished to found a geometry resting on a principle different from the celebrated postulate." It was certainly not *the end* of the eighteenth century, for Saccheri died in 1733. Nor did he wish to set up any geometry different from Euclid, since the very title of his book was 'Euclid vindicated from every fleck.'

"Finally," continues Boyer, "at the opening of the nineteenth century, a Russian, Lobachevski, and a Hungarian, John Bolyai, perceived at about the same time the impossibility of this demonstration." In the index, citing to this page, Boyer gives as the dates of the birth and death of John Bolyai 1775–1856, the dates for his father Wolfgang Bolyai (Bolyai Farkas). Lombroso makes this same confusion and identification of father and son, and from it draws testimony for his thesis that great wits to madness are allied.

John Bolyai (Bolyai János) was born December 15, 1802, and died January 27, 1860. At the celebration of his centenary next year in Hungary I hope to be present. Boyer continues: "Their works published independently of each other had without doubt been inspired by the doctrines of the philosopher Kant who, in a passage of his *Critique of the pure reason*, indicated a new consideration of space. For this latter, space existed *a priori*, precedent to all experience, as completely subjective form of our intuition."

In regard to this bold attribution of influence, I may be allowed to say that not a particle of evidence has appeared to show that John Bolyai ever heard of even the existence of Kant. I examined Bolyai's papers, his correspondence, his 'Nachlass', at Maros-Vásárhely, and never found even the name of Kant. As for Lobachevski, he might have had his attention called to Kant by Bronner the professor of physics at Kasan, at one time an admirer of the 'Kritik der reinen Vernunft,' but that Kant influenced him is merest conjecture, and unnecessary, since we sufficiently know the path of his mental on-going. Of Lobachevski's doctrine, Boyer says, p. 242, "He declares at the beginning the following axiom: through a point can be drawn *many parallels* to a given straight."

What Lobachevski does assume is that through a given point can be drawn innumerable distinct straight lines in a plane which will never meet a given straight in that same plane; but of these, only those two are parallel to the given straight which approach it asymptotically.

Continuing, Boyer says of Lobachevski, p. 245, "When he died in 1856 he occupied the position of Rector of the University which he had entered as simple student."

Unfortunately Lobachevski had been deprived of his position of Rector for ten years before he died.

Passing on to Riemann's geometry, Boyer says: "To construct this Geometry, its inventor rejects the postulatum and the first axiom of Euclid: two points determine a straight."

But the postulatum is: "And if a straight cutting two straights makes with them interior angles lying on the same side, which together are less than two right angles, then the two straights intersect if continually produced on the side upon which these angles lie."

In the 'spherical' or Riemannian geometry

here referred to, so far from this being rejected, it actually remains true. In the 'elliptic' or Clifford-Klein geometry its last clause becomes unmeaning, because the straight line does not divide the elliptic plane into two separated regions. Here we cannot distinguish two sides of a straight. Without crossing a given straight we can pass from any one point of the plane to any other point. In this elliptic geometry, the other assumption mentioned by Boyer, that two straight lines cannot meet at more than one point, is retained. Riemann's epoch-making contribution was that the universe while unbounded still may very well be finite.

This gives us the assumption that a straight line has no point at infinity, that is, that every straight line is actually cut by every other straight line coplanar with it.

Now dropping Euclid's implicit, not explicit, assumption that the straight line is infinite, but retaining all his postulates and axioms, especially Postulate 1 (Simon's Euclid, 1901, p. 30), "Let it be granted that one and only one sect can be drawn from any one point to any other point," we have the elliptic geometry.

On p. 245, line 23, is a misprint, 'joints' for 'points.'

Peirce (C. S.), p. 247, is identified with his father in the index, his name being given as Benjamin and his dates as 1809–1880.

Mr. C. S. Peirce is still alive, having an article in the January, 1901, number of the *Popular Science Monthly,* which contains the charming résumé by Professor Crawley entitled, 'Geometry: Ancient and Modern.' Perhaps it could be wished that this article had more definitely emphasized Euclid.

The advertisement of Boyer's 'Histoire' calls mathematics the science of Euclid and Newton.

In writing of 'The Wonderful Cenury,' Alfred Russel Wallace says of all time before the seventeenth century: "Then, going backward, we can find nothing of the first rank except Euclid's wonderful system of geometry, perhaps the most remarkable mental product of the earliest civilizations."

The new departure, the non-Euclidean geometry, is absolutely epoch-making, but fortunately it has intensified admiration for that imperishable model, already in dim antiquity a classic, the immortal *Elements* of Euclid.

Professor Crawley's exposition of the non-Euclidean geometry is exceedingly interesting. But as soon as it gets beyond two dimensions it becomes obscure.

He says, p. 265, "If we proceed beyond the domain of two dimensional geometry we merge the ideas of non-Euclidean and hyper-space." If we do, we are very apt to blunder. Thus Professor Crawley says, p. 266, "Professor Newcomb has deduced the actual dimensions of the visible universe in terms of the measurement of curvature in the fourth dimension."

This mistake of supposing that a non-Eucidean space requires or needs a space of higher dimensionality has often been publicly corrected.

On page 293 of his 'Nicht-Euklidische Geometrie, I.' Felix Klein puts in pillory the unfortunate title of Newcomb's contribution as follows: "Elementary theorems relating to the geometry of a space of three dimensions and of uniform positive curvature in the fourth dimension. (Die letzten Worte des Titels sind sehr merkwürdig *und deuten auf ein Missverständniss.*)"

After 'we merge the ideas,' Professor Crawley's very next sentence is: "The ordinary triply-extended space of our experience is purely Euclidean." This naïve assertion not only Professor Crawley does not know and cannot prove, but, strangely enough, no one can ever know, no one can ever prove. For Euclidean space the angle-sum of a rectilineal triangle must be exactly two right angles. Such absolutely exact metric results experience can never give.

In connecting a geometry with experience there is involved a process which we find in the theoretical handling of any empirical data, and which therefore should be familiarly intelligible to any scientist. The results of any observations hold good, are valid, always only within definite limits of exactitude and under particular conditions. When we set up the axioms, we put in place of these results statements of absolute precision and generality. In this idealization of the empirical data our addition is at first only restricted in its arbitrariness in

so much as it must seem to approximate, must apparently fit, the supposed facts of experience, and, on the other hand, must introduce no logical contradiction. Thus to-day the ordinary triply-extended space of our experience may be purely Bolyaian, or purely Euclidean, or purely Cliffordian, or purely Riemannian.

In Manning's 'Non-Euclidean Geometry' America has taken a step in advance of all the world in thus putting forth an intended, available class-book for elementary instruction in this fascinating subject.

The book is very gratifying to me, in that the method of treatment that has been taken as the basis of the first chapter is Saccheri's, drawn from my translation, the first ever made, which appeared in the *American Mathematical Monthly*, beginning in June, 1894. My copy of Saccheri is still, so far as I am aware, the only copy on the Western Continent.

It is also matter for congratulation that so many of the further proofs have been taken unchanged from Lobachevski and Bolyai. We rejoice that the world will be rich now in pupils of those who in life had never a disciple.

It perhaps should be noted that though the book says (p. 93), "The Elliptic Geometry was left to be discovered by Riemann," it gives only the simple elliptic, or single elliptic, or Clifford-Klein geometry. It never even mentions the double elliptic or spherical or Riemannian geometry, which Killing maintains was the only form which ever came before Riemann's mind.

GEORGE BRUCE HALSTED.

AUSTIN, TEXAS.

Commercial Organic Analysis. By ALFRED H. ALLEN, F.I.C., F.C.S. Volume II., Part II.; Hydrocarbons, Petroleum, and Coal Tar Products, Asphalt, Phenols, and Creosotes. Third Edition, with revisions and additions by the Author and HENRY LEFFMANN, M.A., M.D. Philadelphia, P. Blakiston's Son and Co. 1900. Pp. viii+322. Price, $3.50.

In the revision of this volume, most of the notes of the second edition have been incorporated in the text, the text condensed to a certain extent, by minor changes, and by omissions, and many valuable additions made. Much matter has been added in regard to the testing of lubricating oils and phenols, and the technology of acetylene. The section on asphalt has been largely increased. The claim of the preface that the nomenclature of the Geneva convention has been applied does not seem justified. Some of the analytical operations are not described in sufficient detail, notably the method for the assay of calcium carbide (page 32). The determination of sulphur in petroleum does not receive the attention it deserves, the most important method—combustion in a current of oxygen or air, and collection of the sulphur dioxide in standard alkali—receiving only passing mention in the section on asphalt. The method for the detection of β-napthol 'suggested' by the American Association of Official Agricultural Chemists was indeed described by the referee in his report, but has not yet been adopted officially by that body. It should be credited rather to Dr. W. D. Bigelow, the referee. It was considered necessary to call attention to these points, but in considering them, the general excellence of the revision should not be lost sight of.

G. S. FRAPS.

L. M. B. C. Memoirs on Typical British Marine-Plants and Animals. Edited by W. A. HERDMAN, D.Sc., F.R.S. V. *Alcyonium* by SYDNEY J. HICKSON, M.A., D.Sc., F.R.S. London, Williams & Norgate. 1901.

A student or amateur zoologist visiting the sea-shore is apt to find the ordinary text-books of zoology somewhat too general to be of much service to him in unraveling the structural details of many of the forms which attract his attention, and the number of forms described in the more special laboratory manuals being necessarily limited, he may find no mention in these of the special organism which interests him. To meet this difficulty the Liverpool Marine Biology Committee has undertaken the publication of a series of memoirs giving detailed descriptions of a number of common animals and plants occurring in the district under investigation by the Committee. The fifth of these memoirs, on *Alcyonium* by Professor Sydney J. Hickson, has just appeared, its predecessor being memoirs on *Ascidia* by Professor Herdman, on *Cardium* by Mr. J. Johnstone, on *Echinus* by Mr. H. C. Chadwick and on *Codium*

by Mr. R. J. H. Gibson and Miss Helen Auld. The editor announces twenty-five other memoirs in course of preparation.

The present little volume, which may be taken as a sample of the series, opens with a brief introduction containing a definition of the order Alcyonaria, and then follow sections on the general appearance of a colony of *Alcyonium digitatum*, its reproduction, the anatomy of the colony, the anatomy of the polyps, the development of the colony and finally its physiology. Three plates containing twenty-four figures complete the little volume, which consists of but twenty-two octavo pages and is sold for the modest sum of eighteenpence.

It is almost needless to say that a description of *Alcyonium* by Professor Hickson is well done, and if the remaining volumes prove as satisfactory as the present one, the editor is to be congratulated upon the initiation of so admirable and useful a series. It would seem that the zoologists of this country might profitably undertake a similar series of memoirs and the idea may be commended to the attention of the officers of the Marine Biological Laboratory.

J. P. McM.

SCIENTIFIC JOURNALS AND ARTICLES.

IN the January–February number of the *Journal of Geology*, Frank Dawson Adams gives an account of 'The Excursion to the Pyrenees in Connection with the Eighteenth International Geological Congress.' The interest centers largely around certain rocks supposed by Lecroix and some other eminent French geologists to illustrate the transformation of limestone into diorite and of shales into gneiss and granite by emanation accompanying granitic intrusions. Professor Adams does not regard the case as proved and suggests, among other things, chemical analysis as a means of testing the hypothesis. O. C. Farrington contributes a discussion of 'The Structure of Meteorites.' They are treated under three classes, iron, iron-stone and stone meteorites. Structures of the monogenic meteorites are discussed crystallographically those of the polygenic according to their mode of aggregation. In a paper entitled 'The Problem of the Monticuliporoidea,' F. W. Sardeson discusses these much neglected although important organisms of the Paleozoic faunas. Unlike many of the recent writers, he has considered them as corals rather than as bryozoans, and several of the commoner forms are described in such detail as to greatly assist students beginning the investigation of these fossils. 'Valleys of Solution in Northern Arkansas' are discussed by A. H. Purdue. They are described as steep and bilaterally symmetrical, with remarkable straightness, due, no doubt, to their connection with jointing planes.

The Botanical Gazette for February contains the first of two papers by Dr. H. C. Cowles upon 'The Physiographic Ecology of Chicago and Vicinity; a study of the origin, development and classification of the plant societies.' Dr. Cowles gives his views on the classification of plant societies, and proposes a method based on the laws of physiography. The general principles outlined in full have been noted already in SCIENCE (Vol. XII., p. 708, Nov. 9, 1900), and are here worked out in connection with the Chicago area. The plant societies are grouped in five genetic series, the first of which, that on rivers, is presented in the first instalment. The paper is illustrated by half-tone reproductions which show the various stages in the development of river-plant societies, from the ravine with its mesophytic slopes, through the xerophytic bluffs stages, and culminating in the mesophytic forest of the flood plain which is regarded as the climax phase of regional development. Mr. John Donnell Smith, publishes his 22nd paper on 'Undescribed Plants from Guatemala and other Central American Republics,' describing about thirty new species from this exceedingly prolific region. Miss Mary H. Smith, of Cornell University, publishes an account of some experiments which would indicate that nitrates are a source of nitrogen for saprophytic fungi. Carlton E. Preston, of Harvard University, publishes a second note on non-sexual propagation in *Opuntia*. Various book reviews, minor notices, notes for students, and news items complete the number.

Torreya is the title of a new monthly journal of botanical notes and news edited for the Torrey Botanical Club by Dr. Marshall A. Howe. A half-tone medallion of Dr. John Torrey, in whose honor the periodical is named, adorns the cover. The object of the journal is to provide a medium for short and semi-popular articles and for reviews, news items, etc., the *Bulletin* of the Club being thus reserved for the longer and more technical papers. It is expected that considerable prominence will be given to notes relative to the teaching of botanical science. The first number of *Torreya* (January) includes the following articles: 'Notes on *Rudbeckia hirta*,' by Dr. N. L. Britton; 'Seedlings of *Arisæma*,' by Dr. D. T. MacDougal; 'Notes on the Genus *Lycopodium*,' by Professor F. E. Lloyd; 'The Summit Flora of King's Mountain and Crowder's Mountain, North Carolina,' by Dr. J. K. Small; 'A simple Dynamometer,' by Dr. H. M. Richards; 'The rare Mosses of Bashbish Falls,' by Mrs. N. L. Britton; and 'Economy in Nature,' by Dr. P. A. Rydberg. The February number contains: 'The Value of Forestry in a Course of Nature Study,' by Miss Elizabeth Carss; 'A new Hygrometer suitable for testing the Action of Stomata,' by Dr. D. T. MacDougal; 'The *Lygodium* at Home,' by Frederick H. Blodgett; 'A new *Senecio* from Pennsylvania,' by Dr. N. L. Britton; and '*Rosellinia ovalis*,' by William A. Riley.

MR. HARRY F. WITHERBY, who has lately made an expedition to the White Nile in search of birds, will commence, in the next issue of *Knowledge*, a series of illustrated articles descriptive of the country, its people, its wild animals and its birds. In the first installment the author deals with his journey by river and the Desert Railway from Cairo to Khartoum, and gives his impressions of Khartoum and Omdurman.

SOCIETIES AND ACADEMIES.

SECTION OF BIOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

THE regular monthly meeting for February was held on the 11th, Professor C. L. Bristol presiding. The following program was offered:

D. T. MacDougal: 'The Critical Points in the Relation of Light to Plants.'

A. G. Mayer: 'The Variations of a Newly-arisen Race of Medusa.'

Dr. MacDougal stated that an examination of all the data at hand shows no correspondence among the maxima, minima and optima of intensities of light with regard to the various influences exerted upon the plant by light, and that the current conception of *phototonus* is not based upon well-defined generalizations. Etiolative phenomena of plants are irritable reactions, consisting chiefly in the elongation of organs which would carry the chlorophyll screens and reproductive bodies up into the light. Light is not necessary to the motility of protoplasm, nor for the activity of the motor mechanisms of such plants as *Mimosa.* The condition known as *darkness-rigor* does not exist. Appearances commonly supposed to be due to rigor of darkness are pathological phenomena occasioned by the disintegration of chlorophyll and other substances. Light may exert a direct chemical (disintegrative) effect upon the constructive material of the cell, but it does not retard growth; on the contrary, it accelerates growth in algæ. Evidence that light exercises a paratonic influence upon plants is not at hand, and no observations could be found by the speaker supporting the conclusion that a similar retarding influence of light upon growth occurs among animals. In discussion of Dr. MacDougal's paper, Mr. M. A. Bigelow called attention to some experiments made by him, under the direction of Professor C. B. Davenport, to determine the influence of light upon embryonic development and post-embryonic growth in Amphibia. Light does not retard, but rather accelerates developmental processes, the effective rays being red in embryonic and blue during post-embryonic stages.

Dr. Mayer stated that in 1898 he had discovered a pentamerous Hydromedusa at the Tortugas, Florida, and had named it *Pseudoclytia pentata.* In this form there are five radial canals, five lips, and five gonads 72° apart, instead of four of these various organs at intervals

of 90°, as in other Hydromedusæ. In its anatomy it is related to the genus *Epenthesis*, being indeed very close to *E. folleata*, which also occurs at the Tortugas. It is probably the descendant of some *Epenthesis*, and seems to be a newly-arisen species. No studies have as yet been made by zoologists upon the variations of such forms. The medusa is highly variable. Out of 1,000 individuals 703 are normal radially symmetrical medusæ, with five radial canals and five lips at intervals of 72°, while 297 are abnormal in some respect, having 4, 3, 2, or 6, 7, 8 canals or lips. It is remarkable that fully 50 per cent. of the abnormal individuals are radially-symmetrical. The greater the departure from the normal form the smaller is the ratio of radially-symmetrical individuals. Thus only 11.2 per cent. of the medusæ having five canals are irregular, while 30 to 33 per cent. of those with four or six canals are irregular; in medusæ with seven or three canals 50 per cent. are irregular, while 100 per cent. of those with two or eight canals are so. The lips show a decided tendency to revert to the ancestral number of four, at intervals of 90°, but the canals, on the contrary, incline toward the higher numbers. We have here a medusa which is continually producing radially-symmetrical sports, and is initiating, so to speak, what might become new species were conditions favorable. On comparing the variations of *P. pentata* with those of *E. folleata* or *Eucope*, one is struck with many remarkable family likenesses. This is especially true in the former comparison. The similarity of the variations, the likeness of their abnormalities in these closely-related forms, indicate apparently a race kinship. The abnormal young of *P. pentata* appear to survive fully as well as normal individuals, and abnormal medusæ mature their gonads quite as commonly as the normal forms. The former are not weeded out by natural selection, yet they have not succeeded in establishing new types of medusæ.

In discussion of Dr. Mayer's paper, Dr. MacDougal spoke of a sport of *Populus tremuloides*, discovered by Dr. Britton, in which the irritability to gravity of the leaves had been reversed so that they now pointed downwards. The reversal appeared in the buds. New plants propagated by grafting retained the positive geotropism of the leaves. It was also stated that the 'weeping' varieties of certain trees were usually produced in this way.

HENRY E. CRAMPTON,
Secretary.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

A REGULAR meeting of the Section was held on February 15th. Dr. D. R. Major reported the results of physical and mental tests on school children of high and of low class standing, the aim of these tests being to discover what relation, if any, exists between class standing and the ability shown in the particular tests used. The tests were as follows: Visual and auditory memory for figures and words, striking out of A's, naming 100 words, copying of figures, weight discrimination, perception of size, sensation-area test as used in the Columbia laboratory, eyesight, age and talkativeness. The tests were made on 150 New York City school children, 68 having high class standing, 82 low. The results of the tests tend to show that the class standing bears a close relation to the ability to pronounce words, to carefulness or accuracy in striking out A's, to memory for words, to eyesight, to age (the average age of the good pupils being less than the average age of the class), and to talkativeness (the good pupils being as a rule talkative). There is apparently little, if any, relation between class standing and the ability shown in the other tests mentioned. The study, however, is not completed and the opinions expressed here are subject to change. In addition to the use made of the standard psychological tests, an attempt is being made to devise tests to determine the presence, nature, and quality or worth of apperceptive activities.

The second paper by Mr. E. A. Spitzka described with special reference to their similarities, the brains of two distinguished physicians, Dr. Edouard Seguin, and his son, Dr. Edward C. Seguin. The most striking similarity discoverable in these brains is the unusual development in the left Insula. This similarity was attributed by the author to heredity, and was

held to be the physical basis for the high type of ability shown by both the Seguins in the use of language. CHARLES H. JUDD,
Secretary.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY OF THE NEW YORK ACADEMY OF SCIENCES

A REGULAR meeting of the Section was held on March 4, 1901. The annual election of officers of the Section was held, Professor William Hallock being elected Chairman and Dr. F. L. Tufts, of Columbia University, Secretary for the ensuing year.

The first paper was by Professor R. S. Woodward and Mr. J. W. Miller, Jr., on 'The Elastic Properties of Helical Springs.' This was part of an investigation now in progress and the details will be published later when the investigation is completed.

Dr. F. L. Tufts then read a paper on 'A Photographic Study of the Air Movements near the Mouth of an Organ Pipe.' In this paper the author described experiments in which he applied the 'method of striæ,' similar to that used by Toepler, C. V. Boys, R. W. Wood and others, to the study of the vibrations within an organ pipe. The pipe used had sides made of plane parallel glass plates. The tongue of air at the mouth of the pipe was made visible by using air mixed with alcohol vapor which changed its optical density. The vibrations and air currents within the pipe were made visible by the introduction into the pipe of small jets of illuminating gas. The intermittent illumination used was the spark between magnesium ribbons from an induction coil. It was found quite easy to adjust the rate of interruption of the coil so as to produce a stroboscopic effect, and thus the movements of the tongue of air in the mouth of the pipe and the vibrations and air currents in the pipe could be readily followed.

The same method was also applied by the author to study the behavior of unignited jets of illuminating gas when acted on by sound waves. The paper was illustrated by a number of photographs of the phenomena observed.

WILLIAM S. DAY,
Secretary.

THE LAS VEGAS SCIENCE CLUB.

THE third meeting of the Science Club was held February 12th. Mrs. Cora W. Hewett exhibited shells of *Pyramidula strigosa* varieties *depressa*, *Cooperi* and *major*, which she had collected between Mora and Peñasco, N. M. It was remarked that, though occurring together, the *depressa* and *Cooperi* forms did not appear to intergrade. Miss Mary Cooper exhibited numerous species of New Mexico Mollusca, including *Ashmunella thomsoniana porteræ* from Manzanares Valley, a new locality. Mr. T. D. A. Cockerell exhibited and discussed a number of shells from a pleistocene deposit at the Arroyo Pecos, Las Vegas. The shells appeared to be all of living species, but he had found in the deposit part of the jaw and a tooth of a species of *Microtus* which, judging from the enamel pattern, was clearly distinct from any species now recognized as living in America. Mr. Cockerell also exhibited specimens of a wax-scale, *Ceroplastes sinensis*, Del Guercio, received from the Agricultural School at Portici, Italy, with the information that it was infesting lemon trees at Chiavari, Italy. It was supposed that the insect reached Italy from China, but it was very close indeed to *C. mexicanus*, Ckll., a species not uncommon in Mexico.

T. D. A. C.

OTTAWA FIELD NATURALISTS' CLUB.

AT the last meeting of the Club held at Ottawa, January 29th, the following papers of special interest to geologists were presented:

Observations on the Crows' Nest Pass. By MR. JAMES MCEVRY, of the Geological Survey of Canada.

Mr. McEvry spoke of the geological structure and economic resources of the Pass and illustrated his paper by means of lantern slides prepared by Mr. J. Keele.

Explorations in Baffin Land. By DR. ROBERT BELL.

This paper gave a graphic *résumé* of the researches carried on by Dr. Bell and his party along the North Shore of Hudson Straits and in the interior of Baffin Land. Numerous lantern slides illustrating the geological struc-

ture and orographic features of the regions traversed accompanied Dr. Bell's paper.

The 'Report of the Geological Section, for 1900–1901,' was then presented by Mr. H. M. Ami, in which were pointed out the nine important discoveries in the Chazy, Trenton, Utica and Lorraine formations in the Paleozoic about Ottawa as well as those in the Pleistocene and marine clays, sands and gravels, etc., of the same district.

H. M. AMI.

SHORTER ARTICLES.

ARSENIC TESTS.

THE note concerning arsenic tests on page 313 of the current volume of SCIENCE brings to my mind some experiments made while testing for arsenic in glycerol, an account of which is found in the *Journal American Chemical Society* for Nov., 1895. I found the destruction of the organic matter (before applying the Marsh test) by a mixture of sulphuric acid and nitric acid (30 to 1) caused a loss of arsenic in some samples but not in others. In one sample treated with this mixture it was found impossible to detect even added arsenic. My conclusion at the time was "that some at least of the samples contain, or are decomposed into, something capable of holding back arsenic. This leads to the query: What is the effect of the combined glycerol present in the toxicological examination for arsenic? May not the trouble with the glycerol be due to a decomposition product which could also be formed in the supposed case?" I have never had time to investigate this point myself, and as far as I know it has never been discussed in print. May not the trouble with the Marsh test as applied to beer be due to the same cause? I was able to detect arsenic in the above-mentioned case by adding the sample diluted with water directly to the reduction flask.

A very simple, convenient and delicate method for detecting arsenic in glycerol is mentioned by several writers. I am not certain who first applied it, but think it was Ritsert. The glycerol is diluted with an equal volume of water, HCl and zinc added, and a yellow coloration obtained, if arsenic is present by exposing filter paper, moistened with either silver nitrate solution (1 to 1) or saturated mercuric chloride solution to the evolved gas. A twenty-five cc. measuring glass is convenient for carrying out the test, the filter paper moistened with the solution being placed over the mouth. This test carried out with mercuric chloride is not as delicate as the Marsh test, but when silver nitrate is employed it is about five times as delicate. E. Ritsert (*Pharm. Ztg.*, 1888, 715 and 1889, 104, 360 and 625) finds this test to show 0.001 mg. of arsenic in 1 cc. of solution where the Marsh test only shows 0.01 mg. in 1 cc.

G. E. BARTON.

MILLVILLE, NEW JERSEY,
Feb. 25, 1901.

PRELIMINARY NOTE ON THE EMBRYOGENY OF NELUMBO.

For two years the writer has had *Nelumbo lutea* under observation and has demonstrated among other points those enumerated below. The discoveries, and the conclusions arising from them, are of such importance that publication in advance of the complete memoir seems advisable. They are as follows:

1. The membrane surrounding the plumule has been shown to be, as conjectured by Wigand, a true endosperm arising within the embryo sac.

2. The embryo is genuinely monocotyledonous in development and the conclusions of Mirbel are erroneous. The plumule arises laterally and at first there is but one cotyledon. Later this bifurcates to form the two fleshy bodies which since Mirbel's researches have been generally regarded as separate cotyledons. For the views of Barthélemy, Richard, Clos and others who have altogether denied the cotyledonary nature of the fleshy bodies, there is no foundation in fact.

3. There is no primary root. The first roots are adventitious and spring from the epicotyl.

Nelumbo, both in its anatomy and embryogeny, conforms to the type of the Monocotyledons and, probably with the other Nymphaeaceae, should be classified in the general vicinity of the Alismaceae.

HAROLD L. LYON.

THE UNIVERSITY OF MINNESOTA,
March 14, 1901.

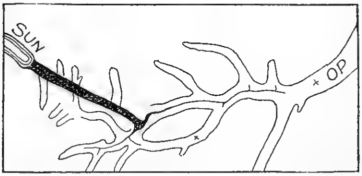
CURRENT NOTES ON PHYSIOGRAPHY.

PHYSIOGRAPHY OF NEW BRUNSWICK.

GANONG continues his 'Notes on the Natural History and Physiography of New Brunswick' (*Bull. Nat. Hist. Soc. New Brunswick*, xix, 1901, 313–340), presenting accounts of the development of several rivers and lakes. The Nepisiguit, for example, is explained as the result of successive captures of portions of three other systems by what is now the lower part of this river. The Negoot lakes, of picturesque outline in a district of primeval forest, are described as resulting from the obstruction of a series of nearly parallel valleys by masses of glacial drift. In the discussion of these problems it is implied that the shores of the Silurian sea are indicated by the present margin of the Silurian strata, that certain existing river courses were determined in pre-Silurian times and that even the valleys of certain rivers and lakes are pre-Silurian; but it is difficult to accept these conclusions on the evidence that is presented. A slight misapprehension as to the meaning of 'monadnock' is indicated in the statement that a hill which rises over the eastern peneplain of Carboniferous strata east of Grand lake is 'not a real monadnock,' for 'it is composed of a ridge of volcanic rocks, and hence remains, not because it is left behind in the general erosion, but because it resists erosion better than the surrounding rock.' It is for such resistant residual mountains and hills that the term monadnock is coming to be generally used.

DRAINAGE CHANGES IN NORWAY.

'THE Sundal Drainage System in central Norway,' by R. L. Barrett (*Bull. Amer. Geogr. Soc.*, xxxii, 1900, 199–219), is an account of a curious series of changes in drainage lines, whereby the upper valleys of the Opdal system that once discharged northeastward into Trondhjem fiord are now discharged northwestward to Sundal fiord. The Opdal system consisted of numerous broadly open valleys with convergent courses and continuously sloping floors. The Sundal, a canyon-like valley, trenches the highlands in which the upper Opdal branches are opened, and receives the waters of several narrow gorges that are eroded in the mature Opdal floors. As a result the lateral stream courses to-day no longer converge towards their trunk, but enter it in a backhanded or barbed fashion;



Sundal system, solid black. Opdal system, outline.

and while the heads of the Opdal system were well enclosed by the highlands, the head of the Sundal system is separated from the head of what remains of the Opdal system only by a flat divide on the mature valley floor. As the gorges and canyons of the Sundal system deepen downstream through the rising valley floors of the dismembered Opdal system, the main Sundal canyon comes to be 1,000 meters deeper than the highest head valleys that it dissects. In explanation of these curious changes, Barrett concludes that normal head ward erosion by the Sundal system is of uncertain and probably small value; westward overflow from ice-dammed lakes that occupied the upper Opdal valleys while the trunk was filled by advancing or retreating glaciers is given more importance; and a still greater share of work is attributed to glacial overflows, when great ice-sheets overwhelmed the region and disregarded the divides that had controlled preglacial river drainage. It is pointed out that the Romsdal, next southwest of the Sundal, exhibits a similar barbed relation between its branch and trunk streams, thus suggesting an interesting field of study for a summer month in Norway.

THE ASSAM EARTHQUAKE OF 1897.

A THOROUGH 'Report on the Great [Assam] Earthquake of 12th of June, 1897,' has been made by R. D. Oldham (*Mem. Geol. Surv.*, India, XXIX., 1899. Pp. xxx + 379 + xviii., 41 pl., 3 maps). This earthquake is said not to have

been surpassed for violence and extent by any of which there is historic record. An area of 150,000 square miles was laid in ruins, all means of communication interrupted, the hills rent and cast down in landslips, and the plains fissured and riddled with vents from which sand and water poured out in most astounding quantities, causing floods in rivers, while a surrounding area of 1,750,000 square miles felt an unusual shock. The earthquake wave is estimated to have traveled at the rate of 120 miles a minute. The amplitude of wave motion near the epicenter was probably 14 inches, and the velocity of wave motion was probably 14 feet a second. It is suggested that the shock may have been caused by a slight movement on a thrust plane, thus accounting for the compression indicated by kinks in railways, and by a slight diminution of north-south distances indicated by a revision of former triangulation. Two hill stations seem to have been lifted by about 20 feet over their former altitude. A number of surface faults are described and figured, one of which had a throw of 25 feet and a length of 12 miles, and another a throw of 10 feet and a length of two and one-half miles. The greater fault produced a waterfall in the Chedrang, and obstructed the Krishnai so as to form a lake several miles in extent, flooding a village and killing a forest of not less than 50,000 *sal* trees. At a certain point in the Himalayan foothills, the steep slopes have been stripped bare by landslides from crest to base, the valley bottoms being piled up with débris and broken trees, producing a scene of indescribable desolation. At this point the landslides usually left a sharp and bare ridgeline, but the crest of one ridge retained a narrow strip of its old forest, although the trees were all broken down by the violent oscillations that they suffered. Many streams, that once consisted of a succession of deep pools and rocky rapids, have been so charged with sand from landslides that their valleys are aggraded and they now flow in broad, shallow, sandy channels. A narrative account of the earthquake has been published by H. Luttman-Johnson (*Jour. Soc. Arts.* xlvi, 1898, 473–493).

W. M. DAVIS.

BOTANICAL NOTES.

TREES OF THE NORTHERN PLAINS.

A RECENT preliminary list of the seed-bearing plants of North Dakota, by Professor Bolley and L. R. Waldron, throws some light on the woody vegetation of the northern portion of the Great Plains. An examination of this interesting list confirms the supposition hitherto entertained that the species of trees are fewer in number as we go north from the central region, there being but twenty-eight, or possibly twenty-nine, different species in the region covered by it. A closer study of the list shows that of these twenty-nine species of trees less than twenty attain to such dimensions as to make them important timber trees, viz.: basswood, sugar maple (a doubtful native species), red maple (more probably silver maple), box elder, red ash, green ash, white elm, red elm, hackberry, western red birch, ironwood, bur oak, black willow, almond willow, American aspen, large-toothed aspen, balsam poplar, cottonwood and red cedar. The other trees are wild red plum, Canada plum, wild red cherry, choke cherry, buffalo berry, two hawthorns, speckled alder, low bur oak and sandbar willow. Of the timber trees, constituting the first list, box elder, red ash, green ash, white elm, hackberry, cottonwood and probably black willow and almond willow occur throughout the State; basswood, both maples, red elm, ironwood, both aspens and balsam poplar are found only in the eastern counties; bur oak in the eastern half of the State; western red birch in the Turtle Mountains (along the Canadian border), and red cedar in the foothills of the southwestern portion of the State. The absence of locusts, sycamores, hickories, walnuts, white oaks, red oaks and pines is a notable feature of the arborescent vegetation of this portion of the plains.

SHRUBS OF THE NORTHERN PLAINS.

THE preliminary list referred to above shows that there are in North Dakota forty-four species of shrubs, a small number when compared with areas of approximately equal extent elsewhere in the United States or Canada. Thus in Nebraska, which is but very little greater in area, there are eighty-six species of shrubby plants.

In examining the list of North Dakota shrubs one is struck by the fact that but five are distinctly western, viz.: skunk bush (*Rhus trilobata*), Western sand cherry (*Prunus besseyi*), Western wild cherry (*Prunus demissa*), Western Juneberry (*Amelanchier alnifolia*), and the silver berry (*Elaeagnus argentea*). These western species may be supposed to have moved from the western mountains out upon the plains, or to have originated here. All the other shrubs are more or less common eastern species which may be assumed to have pushed out from the body of eastern vegetation as has been observed elsewhere on the plains. Among these familiar eastern shrubs are prickly ash, bittersweet, wild grage (*Vitis vulpina* L.), Virginia creeper, smooth sumach, sweet sumach, poison ivy, red raspberry, wild roses (four species), wild gooseberries (four species), cornels (three species), wild honeysuckles (three species), hazels (two species), willows (three species), and junipers (two species). The meadow sweet (*Spiraea salicifolia*), and choke berry, common shrubs of the Eastern States, appear to have entered these northern plains from Minnesota, the Canada buffalo berry from the northeast, and the shrubby cinquefoil from the Rocky Mountains.

NEW EDITION OF THE PHYTOGEOGRAPHY OF NEBRASKA.

THE greater portion of the first edition of the 'Phytogeography of Nebraska,' by Pond and Clements, having been destroyed in the fire which occurred in the publisher's establishment, the Regents of the University of Nebraska authorized a new edition, which has now appeared as a volume of the publications of the Botanical Survey. As the edition is small the distribution of copies is necessarily limited. One hundred copies only have been placed on sale, and when these are sold the edition will be exhausted. The disbursing agent is the University Publishing Company, Lincoln, Nebr. A review of this new edition will appear in a future number of SCIENCE.

BOTANY AND AGRICULTURE.

THE 'Proceedings of the Twenty-first Annual Meeting of the Society for the Promotion of Agricultural Science,' just at hand, is a neatly-printed pamphlet of nearly two hundred pages. An examination of its contents shows that botany as one of several sciences (chemistry, zoology, entomology, meteorology, physics), having relation to agriculture, occupied an unusually large place in the discussions in the New York meeting last June. There were twenty-four papers presented, and exactly one half of these were botanical. Four of the papers had a distinctly horticultural bearing, two were in the domain of plant pathology, two dealt with the chemical aspects of certain plant problems, one discussed weeds, one was in the field of agricultural engineering, and two were devoted to botanical pedagogics. These papers all appear to be more than ordinarily valuable, but those which interest us most are Dr. Trelease's discussion of 'The Botanic Garden as an Aid to Agriculture,' and Mr. Galloway's 'Twenty Years' Progress in Plant Pathology.' It is not within our province to make note of the non-botanical papers, among which are a number of promising titles. The volume is well worth the perusal of every scientific man who is interested in the applications of science to the problems in agriculture.

FIELD ECOLOGY IN THE ROCKY MOUNTAINS.

THE Department of Botany, of the University of Nebraska, offers a course in Field Ecology, to be given in the Rocky Mountains about Pike's Peak during the coming summer. The headquarters of the party will be at Minnehaha, at an altitude of 8,300 feet, from which the plains, foothill, sub-alpine and alpine regions are easily accessible. The work will be under the charge of Dr. Frederic E. Clements, and will begin the first of July and close the first of September. It will consist of a study of the floristics of the various regions, as an introduction to the investigation of the plant formations with respect to their structure and distribution. The special object of the course, however, will be to interpret individual and vegetational adaptations in the light of a thorough examination of the physical factors present, and to determine by experiment in the field the efficient factors in alpine vegetation. A microscopical laboratory with the usual accessories will be fitted up at Spruce Ridge Cottage. There are no fees in connection with the course,

except a registration fee of two dollars for those desiring university credit. The probable expense for the two months, excluding railway fare, will be about fifty dollars.

CHARLES E. BESSEY.
THE UNIVERSITY OF NEBRASKA.

THE NATIONAL BUREAU OF STANDARDS.

THE bill establishing a National Bureau of Standards which, as we have already noted, was passed by Congress at the end of the session is as follows:

Be it enacted, etc., That the Office of Standard Weights and Measures shall hereafter be known as the National Bureau of Standards.

SECTION 2. That the functions of the bureau shall consist in the custody of the standards; the comparison of the standards used in scientific investigations, engineering, manufacturing, commerce, and educational institutions with the standards adopted or recognized by the government; the construction, when necessary, of standards, their multiples and subdivisions; the testing and calibration of standard-measuring apparatus; the solution of problems which arise in connection with standards; the determination of physical constants and the properties of materials, when such data are of great importance to scientific or manufacturing interests and are not to be obtained of sufficient accuracy elsewhere.

SEC. 3. That the bureau shall exercise its functions for the Government of the United States; for any State or municipal government within the United States; or for any scientific society, educational institution, firm, corporation, or individual within the United States engaged in manufacturing or other pursuits requiring the use of standards or standard measuring instruments. All requests for the services of the bureau shall be made in accordance with the rules and regulations herein established.

SEC. 4. That the officers and employees of the bureau shall consist of a director, at an annual salary of $5,000; 1 physicist, at an annual salary of $3,500; 1 chemist, at an annual salary of $3,500; 2 assistant physicists or chemists, each at an annual salary of $2,200; 1 laboratory assistant, at an annual salary of $1,400; 1 laboratory assistant, at an annual salary of $1,200; 1 secretary, at an annual salary of $2,000; 1 clerk, at an annual salary of $1,200; 1 messenger, at an annual salary of $720; 1 engineer, at an annual salary of $1,500; 1 mechanician, at an annual salary of $1,400; 1 watchman, at an annual salary of $720; and 1 laborer, at an annual salary of $600.

SEC. 5. That the director shall be appointed by the President, by and with the advice and consent of the Senate. He shall have the general supervision of the bureau, its equipment, and the exercise of its functions. He shall make an annual report to the Secretary of the Treasury, including an abstract of the work done during the year and a financial statement. He may issue, when necessary, bulletins for public distribution, containing such information as may be of value to the public or facilitate the bureau in the exercise of its functions.

SEC. 6. That the officers and employees provided for by this Act, except the director, shall be appointed by the Secretary of the Treasury, at such time as the respective services may become necessary.

SEC. 7. That the following sums of money are hereby appropriated: For the payment of salaries provided for by this act, the sum of $27,140, or so much thereof as may be necessary; toward the erection of a suitable laboratory, of fireproof construction, for the use and occupation of said bureau, including all permanent fixtures, such as plumbing, piping, wiring, heating, lighting and ventilation, the entire cost of which shall not exceed the sum of $250,000, $100,000; for equipment of said laboratory, the sum of $10,000; for a site for said laboratory, to be approved by the visiting committee hereinafter provided for and purchased by the Secretary of the Treasury, the sum of $25,000, or so much thereof as may be necessary; for the payment of the general expenses of said bureau, including books and periodicals, furniture, office expenses, stationery and printing, heating and lighting, expenses of the visiting committee, and contingencies of all kinds, the sum of $5,000, or so much thereof as may be necessary, to be expended under the supervision of the Secretary of the Treasury.

SEC. 8. That for all comparisons, calibrations, tests, or investigations, except those performed for the Government of the United States or State governments within the United States, a reasonable fee shall be charged, according to a schedule submitted by the director and approved by the Secretary of the Treasury.

SEC. 9. That the Secretary of the Treasury shall, from time to time, make regulations regarding the payment of fees, the limits of tolerance to be attained in standards submitted for verification, the sealing of standards, the disbursement and receipt of moneys, and such other matters as he may deem necessary for carrying this act into effect.

SEC. 10. That there shall be a visiting committee of five members, to be appointed by the Secretary of the Treasury, to consist of men prominent in the various interests involved, and not in the employ of the Government. This committee shall visit the bureau at least once a year, and report to the Secre-

tary of the Treasury upon the efficiency of its scientific work and the condition of its equipment. The members of this committee shall serve without compensation, but shall be paid the actual expenses incurred in attending its meetings. The period of service of the members of the original committee shall be so arranged that one member shall retire each year, and the appointments thereafter to be for a period of five years. Appointments made to fill vacancies occurring other than in the regular manner are to be made for the remainder of the period in which the vacancy exists.

SCIENTIFIC NOTES AND NEWS.

MR. J. J. H. TEALL, F.R.S., has been appointed director general of the Geological Survey of Great Britain and Ireland, in succession to Sir Archibald Geikie, who retired on February 28th. Sir Archibald has been in the service of the Survey for forty-six years and has reached the age limit.

AT a meeting of the Canadian Mining Institute held at Montreal on March 6th, it was unanimously decided to recommend the appointment of Professor Frank D. Adams, as director of the Geological Survey of Canada in succession to the late Dr. Geo. M. Dawson.

A COMMITTEE has been formed to erect at Heidelberg a monument in memory of three of its great scientific men, Bunsen, Kirchhoff and von Helmholtz.

PROFESSOR J. J. THOMSON, Cavendish professor of physics at Cambridge University, has been elected a member of the Athenæum Club under the provision which empowers the annual election of nine persons of distinguished eminence.

DR. M. I. PUPIN, professor of electro-mechanics, at Columbia University, and Dr. R. Mark Wenley, professor of philosophy at the University of Michigan, will represent their universities at the Ninth Jubilee of the University of Glasgow, which takes place in June.

MR. PERCY WILSON, of the New York Botanical Garden, is accompanying Professor Todd's expedition to the Dutch East Indies to observe the total solar eclipse. He will make collections for the Garden.

MR. JARED G. SMITH, of the U. S. Department of Agriculture, left Washington on March 15th for Honolulu, to assume the directorship of the Agricultural Experiment Station.

THE Division of Forestry of the U. S. Department of Agriculture has selected from its working force two trained lumbermen with some knowledge of forestry to be sent to the Philippine Islands in compliance with a cable request of the Taft Philippine Commission. The persons selected for this work are Mr. Grant Bruce, formerly a State forester in New York, and Mr. Edward Hamilton. Both these men are expert lumbermen with some training in forestry, and have been selected in view of their special fitness for the Philippine work. A bureau of forestry was established in the Philippines in April, 1900, with Capt. George P. Ahern, Ninth United States Infantry, in charge.

AT a meeting of the American Academy of Arts and Sciences on March 13th, the following fellows were elected:

Resident Fellows:

ALEXANDER WILMER DUFF, of Worcester, Physics.

THEODORE LYMAN, of Brookline, Physics.

LEWIS JEROME JOHNSON, of Cambridge, Technology and Engineering.

HENRY LLOYD SMYTH, of Cambridge, Technology and Engineering.

FRANK SHIPLEY COLLINS, of Malden, Botany.

EPHRAIM EMERTON, of Cambridge, Political Economy and History.

FRANK WILLIAM TAUSSIG, of Cambridge, Political Economy and History.

Associate Fellows:

ELIAKIM HASTINGS MOORE, of Chicago, Mathematics and Astronomy.

GEORGE ELLERY HALE, of Williams Bay, Physics.

EDWARD LEAMINGTON NICHOLS, of Ithaca, physics, in place of the late William Augustus Rogers.

CYRUS GUERNSEY PRINGLE, of Charlotte, Vermont, Botany, in place of the late George Clinton Swallow.

FRANKLIN PAINE MALL, of Baltimore, Zoology and Physiology, in place of the late Alfred Stillé.

HENRY FAIRFIELD OSBORN, of New York, Zoology and Physiology, in the place of the late Othniel Charles Marsh.

CHARLES OTIS WHITMAN, of Chicago, Zoology and Physics.

WILLIAM STEWART HALSTED, of Baltimore, Medicine and Surgery, in place of the late William Alexander Hammond.

William Williams Keen, of Philadelphia, Medicine and Surgery, in the place of the late Jacob Mandes Da Costa.

Foreign Honorary Members:

Jules Henri Poincaré, of Paris, Mathematics and Astronomy, in the place of the late Francesco Brioschi.

Henrich Müller-Breslau, of Berlin, Technology and Engineering.

Hugo Kronecker, of Bern, Zoology and Physiology, in place of the late Willy Kühne.

Robert Koch, of Berlin, Medicine and Surgery, in place of the late Louis Pasteur.

Sir Thomas Lauder Brunton, of London, Medicine and Surgery, in place of the late Sir James Paget, Bart.

Albert Venn Dicey, of Oxford, Philosophy and Jurisprudence.

William Edward Hearn, of Melbourne, Philosophy and Jurisprudence, in place of the late Charles Russell, Baron Russell of Killowen.

Henry Jackson, of Cambridge, Philosophy and Archæology, in place of the late Henry Sidgwick.

Edmondo de Amicis, of Florence, Literature and the Fine Arts, in place of the late John Ruskin.

Professor Simon Newcomb gave the fourth address of the series on the Progress and Tendency of Science during the Nineteenth Century before the Washington Academy of Sciences on March 19th, his subject being 'The Progress and Tendency of Astronomy.'

Professor Jacques Loeb, of the University of Chicago, read a paper on 'Artificial Parthenogenesis' before the American Philosophical Society at Philadelphia on March 15th.

Dr. Simon Flexner, of the University of Pennsylvania, who went to San Francisco to investigate, on behalf of the U. S. Government, the alleged existence of the bubonic plague in that city, lectured before the Academy of Sciences on 'Defense against Disease.'

George Francis Fitzgerald, since 1881 Erasmus Smith professor of natural and experimental philosophy at Dublin, died on February 21st, at the age of forty-nine years. The Faculty of Science of the newly-constituted University of London has passed the following resolution in his memory:

That this meeting of the Faculty of Science of the University of London, having heard with profound sorrow of the premature death of the late Professor George Francis Fitzgerald, desires to place on record its high appreciation of his brilliant qualities as a man, as a teacher, as an investigator, and as a leader of scientific thought, and to express to his family its mournful sympathy under the calamity which has befallen science and his many friends.

Professor Charles McDonald, for more than thirty years professor of mathematics in Dalhousie College, died in Halifax, N. S., on March 10th.

The death is announced of Mr. R. G. Halliburton, of Canada, known for his political and scientific writings. He was sixty-nine years of age.

Mr. Andrew Carnegie, as all our readers are doubtless aware, has offered to give $5,200,000 to New York City for the construction of buildings for sixty-five branch libraries. The city must provide land and maintenance. The offer has been made in conference with Dr. John S. Billings, director of the New York Public Library, and it is understood that the branch libraries would be administered in connection with the public library. The acceptance of Mr. Carnegie's offer would probably require special legislation, but the city officers have expressed themselves strongly in favor of the plan. Mr. Carnegie has also offered to give $1,000,000 for a library at St. Louis. Mr. Carnegie's gifts and offers awaiting acceptance amount to over $20,000,000, largely for library buildings.

The American Museum of Natural History has recently received a gift of $1,500 from Mr. John L. Cadwalader, of New York, for the purpose of mounting groups of birds illustrating seasonal changes of plumage and other adaptive features of bird life. The fund is to be expended under the direction of Mr. Frank M. Chapman, associate curator.

Mr. Hugh Leonard has given £100 and Sir William J. Farrer £50 to the Royal Institution of London for experimental research at low temperatures.

Mr. Fordham Morris, of New York City, has presented to the American Museum of Natural History a painting representing Audubon with his gun, dog and horses made by his sons, John and Victor, in the late forties a few years before his death. The painting is

now on exhibition in the library reading-room.

THE University College of South Wales and Monmouthshire has received £800 towards the £1,000 required for the Museum of Anatomy proposed as a memorial to Professor A. W. Hughes.

AT a recent meeting of the Canadian Mining Institute a committee was appointed to urge upon the Government an increase of the salaries of those engaged in the Geological Survey, and the need of providing a suitable building at Ottawa for the geological collections.

THE Peary Arctic Club has reelected President Morris K. Jesup, Treasurer Henry W. Cannon and Secretary Herbert L. Bridgman. It likely that a steamer, the fifth, will be chartered and dispatched to find the *Windward*, from which, since the departure from Godhaven, North Greenland, August 20, 1900, with Mrs. Peary and Miss Peary, nothing has been heard.

LIEUTENANT R. F. SCOTT, R.N., the leader of the British Antarctic Expedition, has made to a representative of Reuter's Agency a statement in the course of which he says that the preparations for the British Antarctic Expedition are now practically complete. The *Discovery*, the expedition's ship, will be launched on the 23rd inst., and, after she has been handed over by the contractors, will come round to London, where her equipment and provisions will be put aboard. The *Discovery* has been built on whaler lines, only with greatly increased strength to withstand ice pressure. She is 171 ft. long and 34½ ft. beam, and has 1,500 tons displacement. She will have auxiliary steam, and is fitted with engines of the latest type. In her construction the lines of the *Fram*, though carefully studied, have not been adopted, as Nansen's ship would have been ill-adapted for the heavy seas the *Discovery* will have to encounter. The expedition will leave London in July or August, and will proceed to Melbourne, reaching there in November. The actual work of the expedition will then begin. The naval staff, in addition to Lieutenant Scott, consists of Lieutenant A. R. Armitage (second in command), Lieutenant Charles Royds, and two other officers yet to be appointed. The civilian staff will consist of Professor Gregory, of Melbourne University (director of the civilian scientific staff), Mr. Hodgson (biologist), and Mr. Shackleton (physicist). The medical staff will consist of Dr. Koettlitz and Mr. Wilson.

THE department committee appointed by the British Board of Agriculture to inquire into the conditions under which agricultural seeds are at present sold has completed its report. The committee has come to the conclusion that the seed trade in England is on the whole well conducted and has of late years improved with the advance of science. Nevertheless the majority of the committee recommends that one central station should be provided in the United Kingdom for the purpose of testing the purity and germinating power of seeds sent to it for official examination.

THE British Museum (Natural History) has purchased for £350, an elephant's tusk, which is said to be the largest ever known. The following are its weight and dimensions: Weight, 226½ lbs. Length—outside curve, 10 ft. 2½ in.; inside curve, 9 ft.; base to point in straight line, 8 ft. 2 in. Circumference—at hollow end, 24 in.; at solid 24¼ in. Diameter—at hollow end, 8½ in.; at solid, 7⅞ in.

THE following bill was recommended for passage by the committee on coinage, weights and measures, Mr. Southern, chairman, in the closing days of the last Congress.

A Bill, To adopt the weights and measures of the metric system as the standard weights and measures in the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress Assembled: That on and after the first day of January, nineteen hundred and three, all the Departments of the Government of the United States, in the transaction of all business requiring the use of weight and measurement, except in completing the survey of public lands, shall employ and use only the weights and measures of the metric system; and on and after the first day of January, nineteen hundred and three, the weights and measures of the metric system shall be the legal standard weights and measures of and in the United States.

GOVERNOR ODELL, of New York, has signed

the bill abolishing the Forest, Fish and Game Commission and the Forestry Preserve Board as now constituted—consolidating their departments and placing them under the charge of a State Forest, Fish and Game Commissioner.

THE following bill regulating the practice of medicine has been favorably reported in the New York Assembly by the Committee on Public Health:

Any person shall be regarded as practicing medicine who shall for remuneration, charge, fee, gift, bonus or reward, directly or indirectly profess to heal, or who shall give treatment to any other person by the use of any means or method whatever, whether with or without the use of any medicine, drug, instrument, or other appliance, for the relief or cure of any wound, fracture, or bodily injury, infirmity, physical or mental, or other defects or diseases.

This article is not to apply to any person giving treatment to another under the direction or upon the prescription of a physician, duly licensed by the laws of this State. Neither is it to prohibit the manufacture, sale, or use of patent medicines where no diagnosis is made by the maker or seller; or of the giving temporary relief in an emergency by a registered pharmacist or any person, or the domestic administration of family remedies; or any person in charge of or employed in any gymnasium from giving suggestions or advice as to form or methods of exercise, or any optician engaged in adapting glasses to the sight, or any rights of chiropodists under existing laws, or the manufacture or construction of optical instruments.

THE subjects of the Walker prizes in Natural History awarded by the Boston Society of Natural History are as follows: For 1901: 'Monograph on any problem connected with, or any group belonging to, the North American fauna or flora'; for 1902: (1) 'Nuclear fusions in plants'; (2) 'The fate of specific areas of the germ of chordates, as determined by local destruction'; (3) 'The reactions of organisms to solutions, considered from the standpoint of the chemical theory of dissociation.' Further particulars may be obtained from Mr. C. L. Batchelder, secretary of the Society.

PROFESSOR WILLIAM TRELEASE, director of the Missouri Botanical Garden, has sent out an announcement calling attention to the opportunities offered by the Garden for original research. It calls attention to the fact that in establishing and endowing the Garden, its founder, Henry Shaw, desired not only to afford the general public pleasure and information concerning decorative plants and their best use, and to provide for beginners the means of obtaining good training in botany and horticulture, but also to provide facilities for advanced research in botany and cognate sciences. Persons who wish to make use of these are invited to correspond with the director, outlining with as much detail as possible the work they desire to do at the Garden, and giving timely notice so that provision may be made for the study of special subjects.

DR. B. E. FERNOW, director of the New York State College of Forestry, announces that the spring courses for the junior and senior year students in the College Forest, at Axton, will begin on April 16th and continue until June 13th. In addition to the practical forestry work in silviculture, forest mensuration, surveying, exploitation and forest regulation under the direction of Professers Roth and Gifford, the practical instruction in timber estimating, given last year by Mr. Cyrus P. Whitney, will be repeated. A course of daily lectures on Fish Culture and Game Preservation, beginning April 29th, and lasting two weeks, with laboratory work and field excursions, will be given by Professor Barton W. Evermann, ichthyologist of the U. S. Fish Commission. This course will be open to visitors, as far as accommodations may be found by them in Axton or in the neighborhood.

WE have received the announcement of the twelfth season of the Biological Laboratory of the Brooklyn Institute of Arts and Sciences at Coldspring Harbor, L. I. The laboratory will be open for regular work from July 1st to August 24th, but investigators may make arrangements for a longer residence. A complete series of courses is offered by the Board of Instruction which is as follows:

Professor C. B. Davenport, Ph.D., The University of Chicago, Director of the Laboratory; D. S. Johnson, Ph.D., Johns Hopkins University, in charge of Cryptogamic Botany; Professor Henry S. Pratt, Ph. D., Haverford College, in charge of Comparative Anatomy; Professor Nelson F. Davis, Sc.M., Bucknell University, in charge of Bacteriology; Mrs. Ger-

trude C. Davenport, S.B., Past Instructor Kansas University, in charge of Microscopic Methods; Henry A. Kelly, Ph.D., Ethical Culture Schools, New York, in charge of Nature Study; Lawrence E. Griffin, Ph.D., Western Reserve University, in charge of Embryology; H. N. Whitford, S.B., The University of Chicago, in charge of Phanerogamic Botany; A. G. Mayer, Ph.D., Brooklyn Institute of Arts and Sciences, Lecturer in Entomology; Professor Stephen R. Williams, Ph.D., Miami University, Instructor in Zoology; Professor W. L. Tower, Antioch College, assisting in Microscopic Methods and in Entomology; Louise B. Dunn, Barnard College, assisting in Ecology; A. F. Blakeslee, A.M., Harvard University, assisting in Botany.

THE Summer Laboratory of Biology of Tufts College was established at South Harpswell, Maine, in 1898, and will hold a second session this year. The announcement states that the regular courses of instruction begin on July 8th and continue for six weeks. The laboratory will be established in a small wooden building directly on the shore and will have accommodations for fifteen or twenty students. South Harpswell is situated on the shores of Casco Bay, sixteen miles from Portland. The bay has a rich fauna and flora and is well adapted for a marine laboratory. South Harpswell itself is well situated, as from it one can readily reach the numerous islands of the bay as well as the outer fishing grounds rich in invertebrates. The laboratory is near the extremity of a narrow peninsula (ten miles in length) and being thus almost entirely surrounded by water is free from mosquitoes while hot weather is unknown. Courses will be given by Professor Kingsley and Dr. Lambert on invertebrate zoology, vertebrate zoology, botany and embryology, and facilities are offered to a certain number of students who are able to carry on their researches without assistance.

APROPOS of the movement for an archeological survey of Michigan and legislation to that effect which is now pending, it is of interest to know that Wisconsin students are about to organize a State archeological association, the objects of which are to encourage to a greater extent than is now possible the study and preservation of Wisconsin antiquities and to establish a closer working relationship between collectors and students in different parts of the State.

THE London *Times* states that a further collection of some 400 photographs of objects and customs of antiquarian and historical interest within the British Islands has been made by the National Photographic Record Association and is now at the offices of the Royal Photographic Society, before being deposited in the British Museum. Sir Benjamin Stone's contribution to the present collection is devoted to the county of Warwick. There are two interiors of Trinity Church, Statford-on-Avon, one showing the chancel with its carved oak screen and fine perpendicular windows, and the other a more general view, taken from the extreme west end, in order to give prominence to the unusually placed organ—over the chancel arch. From the same church are illustrations of the fine Elizabethan monument, of the Clopton family, the mayor's pew, and the ancient sanctuary knocker, the seizing of which by a refugee was sufficient to confer upon him the privilege of sanctuary. Outside the church, too, are the shot marks of a military execution. A considerable number of recumbent effigies are taken from the churches of Meriden, Merevale, and Astley. Shakespeare's tomb at Statford-on-Avon is shown when covered with flowers on the occasion of the festival in April last, and various views of the festival procession are also preserved; while the 'Mop' and the roasting of the ox at Stratford are also recorded. Another series illustrates the entire process of haymaking by hand, from the sharpening of the scythe to the stacking—an interesting series of an unusual type, showing a complete industry. Mr. Calcott gives some views of Bristol, St. Peter's Hospital being a particularly fine specimen of carved timber work with the projecting stories supported by animal grotesques. Miss Mary Cotton has contributed some records from the Ardmore, County Waterford, of the Round Tower and ruined cathedral there, and of the ornamental stones known as the Ogham Stones, inscribed only with horizontal lines of various lengths. Of even greater archeological value are Mr. A. R. Hogg's unique photographs from near the Boyne, of the entrance to the Dowth Mound, and the interior of the Tumulus of New Grange, showing the foundation of the stone roof.

Wales is represented by a series of the famous Celtic crosses at Llantwit Major, near Cardiff. A remarkably fine collection of Norman arches, fonts and crosses is sent from Shropshire by Mr. F. R. Armitage. The largest contribution to the collection has been made by Mr. G. Scamell, who has sent over a hundred photographs, principally taken in and around London, of houses once occupied by well known men, houses which are likely to be pulled down soon and, most important, many of the Old Bailey Courts.

UNIVERSITY AND EDUCATIONAL NEWS.

By recent action of the Legislature of North Carolina the annual appropriation to the State University was increased by $12,500; $60,000 was appropriated for the Normal and Industrial School at Greensboro, N. C.; and $40,000 for the Agriculturial and Mechanical College, located at Raleigh, N. C., for payment of debts and buildings.

Henry Stafford Little, of Trenton, has offered $100,000 to Princeton University for the erection of a new dormitory, adjacent to Stafford Little Hall, of which he was the donor.

Harvard University has received $5,000 by the will of the late Jacob Wendell for a scholarship 'to be awarded to a student of excellent standing, exclusive of financial needs.'

Work has been commenced on the new physical laboratory to be erected by the University of Pennsylvania at a cost of $300,000.

The Registrar has just issued the lists of candidates for degrees in Sibley College and other departments of Cornell University. The former numbers about 130; of whom over thirty are in M.E. in electrical engineering, and the remainder mainly in the regular course for M.E., including those in marine and in railway engineering. There will be about twenty candidates for the master's degree, M.M.E. The latter, like M.E., includes marine and railway as well as electrical engineers. The registration of Sibley College is now between 650 and 700, including students engaged in graduate-work and candidates for the second degree. Contracts have just been awarded for the erection of the west central 'dome' of Sibley College, to connect the existing two wings, making a front of about 400 feet, facing the campus from the north. It is to be completed early in the next academic year. It is another step toward the completion of the plans of the founder, by his son, Mr. Hiram W. Sibley. The new building will include new space for the museums and collections and a fine auditorium. This, with accessory extensions of old structures, will add about 20,000 square feet of floor-space to the College buildings. The plans, as prepared for the founder before his death, include further additions of about 40,000 square feet, to give accommodations to a thousand students in mechanical engineering and its subdivisions.

President Patton brought forward some suggestions of much importance at a meeting of the trustees of Princeton University on March 15th, and these were referred to a special committee. They include: (1) Additions to the faculty that will enable the University to offer courses in human anatomy and physiology and in common law, so that students may take in their senior year the equivalent of the first year in professional schools of medicine and law; (2) making it possible for students doing additional work to secure the bachelor's degree in three years; (3) offering additional lectures in the sophomore year.

It appears that the disturbances in the Russian universities are continuing, it being reported that 700 students have been arrested at Moscow.

At Yale University the following instructors have been promoted to assistant professorships: E. W. Scripture in psychology; A. W. Evans in botany, and H. E. Gregory in physical geography.

At Princeton University, Dr. W. M. Rankin has been promoted to a full professorship of invertebrate morphology, and Dr. C. F. W. McClure to a full professorship of comparative anatomy.

Dr. Peter Guthrie Tait, since 1860 professor of natural philosophy at Edinburgh University, has resigned his chair on account of ill health.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE EMBRYOLOGICAL BASIS OF PATHOLOGY. *

EMBRYOLOGY is the basis upon which pathological science must be erected. Pathology is even more a superstructure upon embryology than is anatomy. Anatomy, in its descriptive form, may stand by itself and have usefulness. Pathology cannot be built up as a merely descriptive science. It fails of its true purpose unless it discovers the causes of diseases. Now since function is dependent on structure, the aim of the pathologist must be first to discover the causes of morbid structure. In brief, pathology at the present time deals chiefly with problems of the development of anatomical forms. Pathology and embryology might almost be united in a single comprehensive study—morphogeny. Let us then try, for this evening at least, to free ourselves from the conception of an essential difference between normal and abnormal structure, a conception which, I believe, domineers too largely over our daily thoughts. This belief of mine I hope to justify to-night.

Simple description is indispensable, it furnishes the virgin facts; but facts do not develop by parthenogenesis into science; they must be saturated with the stimulus of study, with the stimulus of knowledge of their history, their antecedents, their causation, then we may see them evolving

* The Middleton Goldsmith lecture delivered before the New York Pathological Society, March 26, 1901.

themselves into new orders, which we call natural laws. As little as a description of the people of the United States with no information as to their history could satisfy a serious thinker, so little can descriptions of fully developed structures satisfy an earnest pathologist. An innate, intense mental impulse is continually driving us forward in the search for causes, and obedience to this impulse is one of the main factors in scientific progress. All this is familiar, trite even, but may serve to fix our starting thought, namely, that we are to study causes.

Our attention is to be directed to the consideration of what embryology can teach us in regard to the causation of organization, and then to the application of those teachings to pathology.

This plan will exclude from our discussion many of the aspects of embryology which appeal most strongly to pathologists. We must omit from our study at least three groups of interesting phenomena, to wit: *First*, the arrests of development; *second*, the teratological formations, monstrosities and mis-developments, which will, however, have to be included ultimately even in the precise field we are about to study; *third*, the so-called teratoma, or to use a more recent term, embryoma. I may say in passing that I find it very difficult to accept the hypothesis that these remarkable structures arise by a parthenogenetic development of ova, retained in the parent body. Professor Bonnet's hypothesis is more legitimate, but towards that also my attitude is one of sceptical agnosis. Bonnet suggests that one of the early segmentation cells (blastomeres) may become isolated and retarded in its development, remaining as an inclusion in the fœtal tissues, and afterwards develop and produce a variety of tissues, as isolated blastomeres have been shown by experiments on the lower animals to be capable of doing.

Teratological formations fall, it seems to me, naturally into three fairly definite divisions: (1) those due to necrosis of the tissues, which apparently rarely if ever takes place uniformly throughout the embryo; (2) those due to gross mechanical disturbances of the development, consequent upon failure of the proper correlation of the growth of parts; monstrosities of this division are probably the most common; (3) errors in the differentiation of the tissue or pathological histogenesis. It is only phenomena of the first and second divisions of teratology which we can safely drop from view, while those of the third division—errors in differentiation—we must bear uninterruptedly in mind.

One more preliminary explanation is necessary. The range of pathological changes is not so great as to reach equality with embryological developments. In the normal embryo we deal with the evolution of complete organs together with all their accompanying varied and complex modifications of tissue. In pathology, on the contrary, we deal not with organs, but with modifications of tissues, with histogenesis. The statement will not seem too absolute if it is recalled that we have excluded arrests of development and monstrosities from our discussion.

Histogenesis is the common territory in which the pathologist and embryologist have —to borrow a legal phrase—an undivided interest. It is unfortunate that our tendency has so long been to attempt an unnatural and impossible partition of the territory, which has resulted only in a division of our forces into two camps, between which has reigned little interest and less sympathy. I venture to regard your invitation to address you to-night as a wish, which I fully share, to secure fuller cooperation between the two camps of workers, who are both striving to lay bare the laws which govern the differentiation of cells.

After these preliminary explanations it is possible to define the evening's task with precision. It is twofold. First, to present some of the more important conceptions derived from embryological study in regard to the processes of cell differentiation. Second, to suggest some of the bearings of these conceptions on the problems of pathology.

PART I. NORMAL DIFFERENTIATION.

Under this head I propose to discuss three fundamental ideas:

First, of the undifferentiated cell.

Second, of the progress of differentiation.

Third, of the changes which may succeed differentiation.

The fertilized ovum is an undifferentiated being, although it has a very complex organization, and contains besides the protoplasm a store of nutritive material, the so-called yolk or deutoplasm. As there is only one nucleus, there can be no variety of nuclei; the term undifferentiated, therefore, applies to the protoplasm, which seems to have a uniform essential structure throughout, although the masses and strands of protoplasm may exhibit characteristic peculiarities, especially in relation to the distribution of the yolk. In the adult, on the contrary, the protoplasm of the cells of different tissues offers many varieties of essential structure, which can often be readily distinguished under the microscope. It is a legitimate conclusion that the absence of visible peculiarities of the intimate structure of egg protoplasm, by which one part may be distinguished from another, corresponds to uniformity of structure throughout the egg, excepting, of course, certain special characteristic arrangements, as, for example, the centering about the centrosome, which may occur in any cell.

We have also direct experimental proof that the egg is uniform throughout, or to use a better phrase, that the egg is isotropic. Pflüger, in 1884, proved that the side of the frog's egg, which normally develops into the ventral surface of the embryo, can be made to develop into a perfectly typical dorsal surface. The frog's egg has a small white area, which normally lies underneath, the larger darkly pigmented area of the egg alone showing from above. Out of the dark area the back with the nervous system and other parts takes its origin. If the eggs, freshly fertilized, are fastened with the white side up, then the white side produces an absolutely normal back and nervous system, normal as to form and function, though lacking the typical pigmentation. These observations were confirmed by Born, who further discovered that the segmentation nucleus always rises towards the upper side of the egg, and that the position of the nucleus determines which part of the ovum shall become the dorsal side of the embryo. Another set of experiments by Oskar Schultze demonstrated that both the unpigmented and the pigmented sides of the same egg could be made to produce dorsal structures.

Another class of experiments, which were first made by Hans Driesch, have demonstrated that the earliest cells (segmentation spheres, blastomeres or cleavage cells, as they are variously called) produced by the ovum preserve the undifferentiated qualities of the parent egg, and may develop in one way or another according to circumstances. The egg of a sea urchin divides into two cells, each of which multiplies and normally gives rise to half* of the body of the animal. By somewhat violent shaking the two cells may be artificially separated; each cell may then develop into a complete larval sea-urchin, but of half the normal size only. Similar experiments have since been made by several investigators, who have obtained like results with

* It would be safer to say supposedlv about half.

other animals, vertebrate as well as invertebrate. Even more remarkable larvæ have been raised from blastomeres of the four cell and eight cell stages of segmentation, producing larvæ of one-fourth and one-eighth the normal size. Zoja claims to have repeated the experiment successfully on the eggs of *Clytia* and to have obtained one-sixteenth larvæ.

The facts offered suffice to illustrate the two aspects of our conception of the undifferentiated condition of living matter. The first aspect is morphological and presents to us the apparent uniformity of the visibly minute structure of protoplasm. While we readily admit that the uniformity may be only apparent in the sense that we fail to observe fine differences, yet we none the less maintain that the uniformity is real, because there is an absence of variations of structure comparable to the variations which we can observe in the cells of adult tissues. The second aspect is physiological and offers to our view the wide range of possibilities in the future developmental history and growth of the protoplasm. The fate of the protoplasm of any given part of the ovum is not fixed, but if its conditions of development are changed its fate is changed. A few years ago the mosaic hypothesis was advanced by W. Roux and has been vigorously defended by him. According to the mosaic theory, the egg is a mosaic pattern, each member of which has its predestined history. It is fortunate for our comprehension of pathological process that we are already able to say that Roux's hypothesis is erroneous.

We must start then with the right conception of the ovum, every part of the protoplasm of which is to be regarded as potentially capable of producing any or all the tissues of the adult.

We turn next to the consideration of the progress of differentiation in order to establish a second fundamental idea, namely, that it acts as a progressive restriction of the further development. Each successive stage of differentiation puts a narrower limitation upon the possibilities of further advance. Applied to pathology, this law means that the range of possible pathological changes is determined not merely by the nature or kind, but also by the stage or degree, of the previous differentiation of the tissue.

The eggs of all animals* pass through two well-marked phases of development.

During the earlier and much shorter phase, the nuclei are multiplying rapidly, while the cytoplasm is growing but little, if at all. This period includes the time of segmentation, as commonly described, and somewhat longer. During this period the total bulk of the nuclei in proportion to the protoplasm is fundamentally changed. The ovum arises from a cell, the ovocyte, which, as its last act, grows rapidly ; this enlarged cell, by the process of maturation gives rise to the female sexual element, which has a single nucleus. After the fertilization we have an ovum with much protoplasm and deutoplasm, but again with only the single segmentation nucleus. The development of each individual begins, therefore, with a cell in which the extreme disproportion between the size of the nucleus and of the whole cell-body occurs. The first effort of development is to correct this disproportion by the enormously rapid increase of the nuclei, which continues until cells of the embryonic type are produced, that is to say, cells each with a minimal amount of protoplasm around the nucleus. With the production of cells of the embryonic type, the first phase of development is completed. The limits of this phase are very indefinite for we observe often that the prodution of cells of the type defined may be far advanced in one part of the germ, while it is

* The protozoa are obviously excluded from the present discussion.

still in early progress in another. In fact the phase has no exact boundary in time.

During the second, later and much longer period or phase of development, the multiplication of nuclei lags behind the growth of the protoplasm; the increase is gradual and often shows itself through successive generations of cells, sometimes, however, in a single cell, which no longer multiplies. Of the first method of protoplasmic growth embryonic blood-cells offer a good illustration, of the second the neuroblasts or young nerve cells afford a striking example. Now cells of the embryonic type show little if any capacity for differentiation, and the increase of the protoplasm in the single cell is, so far as we can judge, a necessary preliminary step to cell differentiation. The embryonic cells have yet another characteristic of basal significance; they are capable of rapid multiplication. Hence we conclude that the growth of the cytoplasm impedes the multiplication of cells, and, therefore, ultimately retards the growth of the body, as a whole, while on the other hand it favors differentiation. Accordingly the growth of cells and their differentiation are essentially antagonistic processes, which are necessarily more or less mutually exclusive. This conclusion which I published in 1890, has since been amply confirmed by further observation. It is probably applicable alike to animals and plants, alike to normal and abnormal tissues. It is one of the many conclusions of embryology which are sure to throw a revealing light upon some of the dark problems of pathology.

During the first phase of development, as just defined, we encounter preparatory changes which we may characterize summarily as the manufacture of embryonic cells. During the second phase, though the production of embryonic cells is doubtless continued in certain regions, there supervenes the process of differentiation, the true histogenesis.

After segmentation there follows the formation of the germ layers, a gradual arrangement of the cells in three distinct primary strata—at least in all vertebrates there are always three strata, never more* nor less. The outer and inner layers, ectoderm and entoderm, very early become distinctly epithelial. The middle layers become partly epithelial, partly of a special character, that is mesenchymal. At first one is inclined to think of the difference between epithelium and mesenchyma as a fundamental one, an early and unalterable separation of cells into classes. This view finds support in the fact that the mesenchyma, and it only, produces in the course of further development the connective tissue and supporting tissues of the adult. More attentive study of the germ layers in early stages reveals, however, that the mesenchymal cells arise from the epithelium, single epithelial cells migrating from the parent territory, while on the other hand groups of mesenchymal cells rearrange themselves so as to form an epithelial covering of some surface, as for example, in synovial cavities, arachnoid spaces, the inner surface of the cornea, lymph vessels, etc. Such observations teach us that we must not assume that either the form or the arrangement of cells is necessarily and always a sign of true differentiation, but that instead we are to conceive of differentiation as a change in the intimate and essential structure of the individual cell, more specifically of its protoplasm, and perhaps of its nucleus. The rôle of nuclei in histogenesis is a topic which unfortunately is still awaiting serious investigation. To resume: it seems to me probable that the cells of the germ layers are at first quite

* Hertwig and some other German embryologists divide the mesoderm into two layers; the division is contrary to the actual development, and is made, in my opinion, quite arbitrarily to satisfy the needs of an erroneous theory.

indifferent, so that if it were possible to graft a young mesodermal cell on to the ectoderm or entoderm, it would become a true ectodermal or entodermal cell, as the case might be.

But although we may, so far as we now see, regard the cells in the germ layers as originally wholly indifferent as individual cells, nevertheless, we must not forget that as members of a germ layer their potential fate is already restricted by the conditions of their very layership—if I may coin a word for the occasion. Each layer produces its own group of tissues and never any other. There are indeed apparent exceptions to the rule, as, for example, the stratified horny epithelium of the œsophagus, which is strikingly similar to the epidermis, although in one case the tissue is ectodermal, in the other entodermal. We have, however, to do only with a resemblance, and the development in the two cases is quite unlike—the œsophageal epithelium in the mammalian embryo being ciliated at one stage and exhibiting then little resemblance to any stage of the epidermis.

Each germ layer has its specific function, its exclusive share in the work of differentiation. The work of one layer is not done by another nor shared by another. It is true that attempts are made from time to time to upset the validity of this fundamental doctrine, but they have hitherto failed to find support or recognition from any leading embryologist, and I deem these attempts unworthy of serious consideration. We are able now to assign almost every cell of the normal adult human body to its proper germ layer. Our only great uncertainty is where two layers meet, as do the ectoderm and entoderm in the pharynx, or as do the mesoderm and entoderm, where the ureter opens into the bladder. With these and perhaps a very few other small exceptions everything in adult anatomy can be correctly stated in terms of germ layers. The layership of every organ is known, save that in the cases of the thymus gland, the tonsils and the adrenals authorities are not yet agreed.

A remarkable attempt to upset the doctrine of the germ layers deserves a brief consideration. It was first maintained by Goronovitch that the cells forming at least a part of the skeleton arose from the ectoderm. The same opinion was expressed also on the basis of their own investigations by H. Klaatsch and by Miss Platt. Confirmation of these views has not followed, but on the contrary, C. Rabl, one of the most trustworthy of living observers, maintains that essential parts of Goronovitch's and Klaatsch's evidence are simply errors of observation. Klaatsch's views were based partly on the study of the developing teleost fins. R. G. Harrison has shown that here the German worker is in error. Miss Platt's observations were made in the head region of embryo Necturus. An examination of a number of series and stages has not enabled me to find the slightest evidence in favor of Miss Platt's conclusions. H. K. Corning has pointed out that the processes alleged by Miss Platt to occur in Necturus do not take place in the frog, *Rana temporaria*. We may, therefore, I think, safely regard this attempt to overthrow the morphological value of the germ layers as unsuccessful. I know of no other attempt of sufficient importance to be even mentioned.

The importance to pathologists of a thorough knowledge of the genesis of the tissues from their germ layers can hardly be emphasized too strongly, for it is more than probable that all pathological tissues are as strictly governed by the law of the specific value of germ-layers as are the normal tissues. Are there not many pathologists whose knowledge of embryology is wholly insufficient to meet the practical needs of

their professional study even in this one direction?

The accompanying table presents the principal tissues classified according to their layership. There have been classifications of organs on the layership basis published before, but inasmuch as organs usually contain cells from two layers, we get a more correct presentation of the actual genetic relationships by restricting our tabulation to the tissues. Leucocytes do not appear in the table for the reason that their first origin is uncertain. Blood cells arise very early, before the clear separation of mesoderm and entoderm has occurred—it is possible that they are entodermal. With these two limitations, the table presents our present knowledge.

CLASSIFICATION OF THE TISSUES.

A. ECTODERMAL.	B. MESODERMAL.	C. ENTODERMAL.

c. Ganglia.	g. Marrow.	c. Respiratory tract,
d. Neuraxons.		Larynx,
		Trachea,
		Lungs.

We will now turn to the analysis of the differential process in each germ layer. We have to deal with changes in cells.

There are two distinct types of cell differentiation, which I think have not hitherto been clearly recognized or defined. For both types the starting point is the same, the undifferentiated embryonic cell. In one type we find that as the cells proliferate, a portion of them only undergoes differentiation, and another portion remains more or less undifferentiated and retains more or less fully the power of continued proliferation. The epidermis is a good representative of this type. Its basal layer consists of embryonic cells, which multiply; some of these cells move into the upper layers, enlarge and differentiate themselves into horny cells; others remain in the basal layer and continue to multiply. The progeny of a given basal epidermal cell do not all have the same fate, but divide themselves into two kinds of cells, one kind retaining the ancestral character, the other becoming something new and unlike the parent cell. Differentiation according to the second type is characterized by its inclusion of all the cells. This type has its

culminating and most perfect illustration in the central nervous system, where comparatively early in embryonic life all the cells become specialized, and with the acquisition of specialization they forfeit their power of multiplication, the neuroglia cells partly, the nerve cells wholly. The growth of the brain after early stages depends not on proliferation of cells, but chiefly upon the increase in size of the individual cell. The correctness of this statement is not affected, in my belief, by the fact that epithelial portions of the medullary tube in comparatively late stages may be added to the nervous portion, the cells multiplying rapidly, as we see at the growing edge of the young cerebellum. The brain here grows by the addition of cells in the indifferent stage, but as soon as these cells are differentiated they conform to the general law and divide no more (neurones) or slowly (glia cells).

The two types of differentiation produce essentially unlike conditions. The pathologist may not overlook such unlikeness with impunity. The two types pass into one another with many intergrades. Hence when we consider the possibilities of pathological alteration we must in each case seek to determine how far the condition of the tissue involved permits cell multiplication, as well as differentiation.

Just as the segmentating ovum divides itself into parts, which we name germ layers, each of which has its special and exclusive share in developing the adult tissues, so does each of the three germ layers divide into parts, each part having its special and exclusive roll, and these parts again subdivide until, after the final partition, the adult variety is produced. During all these changes there is no exchange of rôles. It will be profitable to let the phenomena pass before us in rapid review.

First, then, the ectoderm. This layer early separates into two parts; one to form the central nervous system, the second the epidermis; the nervous part thereafter never forms epidermal structures, the epidermal part never forms a nervous system. The central nervous system retains in part a simple epithelial character, but most of its walls become nervous tissue; its cells pass from the indifferent stage and become neuroglia cells or young nerve cells (neuroblasts). Neuroglia cells never become anything else, and the nerve cells are always nerve cells to the end. The primitive epidermis forms a series of special sensory areas and the permanent epidermis. The sensory areas, which belong to the olfactory, auditory and gustatory organs, soon become well defined and never produce any cell arrangements like those of the epidermis. This last, on the contrary, remains as before stated, rich in undifferentiated cells, and gradually produces a great variety of structures. Most of these, namely, the hairs and glands, are small and very numerous, while a few like the nails, enamel organs and epithelium of the lips are larger. No one of these special structures, however, converts itself into another. The basal layer of the general epidermis may perhaps preserve a true embryonic quality and have wide differential possibilities.

Next, as to the entoderm, which undergoes less differentiation than either of the other two germ layers, since over a large part of its extent it remains throughout life a simple epithelium with many cells very slightly modified in structure. Wherever in it specialization takes place, as in the tonsil, thymus, thyroid, œsophagus, liver or pancreas, each territory of cells keeps its characteristics and never assumes those of another territory.

Finally as to the mesoderm, in which layer variety of differentiation attains its maximum. To follow the genesis of this variety is most instructive. The mesoderm

is found very early to include in vertebrate embryos, four kinds of cells, of which the most numerous are undifferentiated cells, the other three kinds being (1) endothelial cells of blood vessels; (2) blood cells; (3) sexual cells; all these are precociously specialized; they are few in number, yet they are probably the parents of all the cells which are produced of their kind throughout life. Our present knowledge does not permit us to speak with entire certainty, but the evidence is strongly in favor of the following three conceptions:

First. That all the endothelium of the blood vessels of the adult is descended directly from the endothelium of the first blood vessels differentiated in the extra-embryonic portion of the germinal area.

Second. That all the red blood corpuscles are descendants from the red-blood-cells of the blood-islands of the area vasculosa. According to this view the blood forming organs, as they are called, merely provide sites, where the red cells can multiply, as for instance in the mammalian embryonic liver or in the adult marrow.

Third. That the primitive sexual cells by their multiplication produce all the cells from which the genoblasts, or sexual elements proper, male and female, are evolved.

The future will decide the validity of these conceptions. They are very significant, because they assume that there are cells which form exclusive classes, and are characterized by a special combination of qualities, so that while they retain so much of the embryonic character as to have still the power of rapid multiplication, they yet are so specialized that they can only produce their like. If the three conceptions are established, we shall regard these three sorts of cells as almost the first to be fully differentiated. We shall also have to regard the vascular endothelium as distinct not only from the epithelial lining of the body cavity, but also from that of the lymphatic system. The immense importance of such a discovery as bearing upon pathological researches and interpretations is obvious.

The next important change in the mesoderm is the development of the main body-cavity, which the embryologist designates comprehensively as the cœlom. The cells, which lie next the body-cavity and border it, assume an epithelial arrangement; this epithelial layer around the cœlom is properly named '*mesothelium*,' and the loose cells about it constitute the '*mesenchyma*.' We do not have, however, at first a true differentiation of mesothelial and mesenchymal cells; all are undifferentiated, and we can readily demonstrate that the cells are interchangeable, differing during early stages by their positions in relation to one another and to the body cavity, but not differing in their essential structures or qualities. Thus we find that the mesothelium constantly gives off cells which join the mesenchyma, and we find later that mesenchymal cells may take on an epithelial arrangement around any of the cavities—and there are many such—which arise within the mesenchyma itself in the course of further development.

But, although difference of arrangement does not necessarily indicate differentiation of the cells, it does affect the character of the differentiation which ensues. As every text-book states, the mesothelium gives rise to the striated muscles and to the epithelial portions of the entire genito-urinary tract, and is permanently retained, with slighter modifications, as the epithelium of the pericardium, pleuræ and peritoneum. The mesenchyma produces an even greater variety since it is the parent of not only all the connective and supporting tissue, but also of the lymphatic system.

I venture to turn aside for a moment to urge upon you the adoption of the term mesothelium as the correct designation for the

epithelial lining for the cavities of the thorax and abdomen. It is literally the same epithelium in the four cavities, for they were originally one, with a single continuous epithelium. It is well also in our nomenclature to recognize the important fact that the epithelium is radically, because genetically, distinct from the endothelium of the blood vessels and lymphatics, and the application of the term 'endothelium' to the covering of, for instance, the peritoneum, leads and can lead only to confused bad thinking. If mesothelium be employed as suggested, clearness will be gained.

Coming back now to the subject of the mesoderm, let us note that when a striated muscle fiber is produced a striated muscle fiber it always remains, and it never becomes anything else; the ovary never changes. In short, with the mesoderm as with the ectoderm and entoderm, we see the fate of the cells once fixed to be thereafter unchangeable as to the kind of differentiation.

Our hasty review is worse than imperfect, yet is sufficient to impress upon us the great law that differentiation in any direction terminates the possibility of differentiation in any other direction. In accordance with this law we encounter no instances, either in normal or in pathological development, of the transformation of a cell of one kind of tissue into a cell of another kind of tissue, and further we encounter no instance of a differentiated cell being transformed back into an undifferentiated cell of the embryonic type with varied potentialities.

Thus far I have expressed myself somewhat as if there were two sharply defined conditions, the differentiated and the undifferentiated. To give such an impression would be to create error, since differentiation is a slowly progressive and wholly gradual change in the cell. We must look upon each step in the process of differentiation as establishing narrower limits for future changes. Thus, when in the spinal cord neuroblasts diverge from the glia cells, they are not specialized into different classes of neuroblasts; such specialization comes later. So in the mesenchyma after the embryonic cells have changed and large numbers of them have become connective tissue cells, these last still are capable of various further differentiations, and may, therefore, be said to have been arrested in their development at a stage of partial differentiation. This quality of the connective tissue cells is, from the pathological standpoint, one of the most important facts known to us concerning the structure of the body.

Having now elaborated, as far as time permits, our conception of the nature of differentiation, let us turn to our third fundamental idea, which concerns the changes which succeed differentiation. These changes are very unlike the constructive changes which precede them, for they are destructive. They fall into three main groups:

1. Changes of direct cell death.

2. Necrobiosis,* or indirect cell death preceded by changes in cell structure.

3. Hypertrophic degeneration or indirect cell death preceded by growth and structural change of the cell.

Of direct cell death no discussion is here necessary, for the fundamental idea, which I wish to emphasize, is that necrobiosis and hypertrophic degeneration are normal processes, which invariably occur in the normal body and play in many cases important rôles in the life history of the individual. Without necrobiosis and degeneration on a large scale, the normal round of human life would be impossible. It is singular that in treatises on normal anatomy and

* It is a matter for regret that so awkward a term as 'necrobiosis' should have become current.

histology these two subjects are generally neglected or at most appear only as matters of incidental reference. The force of tradition makes us apply these terms as if they correspond exclusively to pathological conditions. This tradition might still prescribe our mental attitude, were it not that the studies of the last dozen years have made us familiar with the enormous extent, variety and rapidity of the destructive degenerations which go on in the pregnant uterus of placental mammals, a degeneration which takes place without affording a trace or a suggestion of any pathological modification whatsoever of the organ. To our inherited prejudices the uterine phenomena alluded to are startling, but their evidence before the tribunal of biology has settled the case in favor of the plea that hypertrophic degeneration is a normal factor in typical healthy development.

The normal and pathological changes associated with the death of cells, and consequently also of the tissues which are formed by cells, are so nearly identical that they may be combined in a single discussion. For the more convenient presentation of the subject the following table has been prepared. Concerning the table little explanation is necessary.

A few special points need mention. The distinction made between necrobiosis and degeneration corresponds to recognizable differences, but our present knowledge is insufficient to provide clear definitions for the two closely related types of indirect cell death. I feel much doubt as to the propriety of including *atrophy* in the table at all, since it seems to me that we ought, perhaps, not to regard atrophy as a phenomenon of a distinct class, but merely as a result of necrobiotic or degenerative alterations in cells and organs. Under the heading 'degeneration' the division into 'cytoplasmic' and 'paraplasmic' takes us beyond our present knowledge, while the division 'nuclear' is added rather to satisfy a biological conscience than to represent a part of our knowledge.

Death of Cells.

First—Causes of death.
- a. External to the organism.
  - 1. Physical (mechanical, chemical, thermal, etc.).
  - 2. Parasites.
- b. Changes in intercellular substances (probably primarily due to cells).
  - 1. Hypertrophy.
  - 2. Induration.
  - 3. Calcification.
  - 4. Amyloid degeneration.
- c. Changes inherent in cells.

Second—Morphological changes of dying cells.
- a. Direct death of cells.
  - 1. Atrophy.
  - 2. Disintegration and resorption.
- b. Indirect death of cells.
  - 1. Necrobiosis (structural change precedes final death).
  - 2. Hypertrophic degeneration (growth and structural change often with nuclear proliferation precede final death).

Third—Removal of cells.
- a. By mechanical means (sloughing or shedding).
- b. By chemical means (solution).
- c. By phagocytes.

The preceding table represents the only attempt of the kind known to me, and like other first attempts is undoubtedly very imperfect. It embodies obviously no new facts. But, because it is frequently a scientific gain to systematize our information, I hope the table may be useful, and it will certainly serve its immediate purpose, namely, to guide our discussion of the normal changes which follow after cellular differentiation.

As the time at our command is brief let us pass by the consideration of the causes of cell death. I will remark only that I think amyloid degeneration may be found to occur in the placental decidua of the human pregnant uterus and perhaps in other normal structures. No positive information

on this point is known to me. For the reasons stated a few minutes ago atrophy may also be omitted here. We pass by also the direct forms of cell death, to reach at once the consideration of the indirect forms.

The accompanying table offers an analysis of some of the principal varieties of structural change, which occur during indirect cell death.

Indirect Death of Cells.

- A. *Necrobiosis.*
  - 1. Cytoplasmic changes.
    - a. granulation.
    - b. hyaline transformation.
    - c. imbibition.
    - d. desiccation.
    - e. clasmatosis.
  - 2. Nuclear changes.
    - a. karyorhexis.
    - b. karyolysis.
- B. *Hypertrophic degeneration.*
  - 1. Cytoplasmic.*
    - a. granular.
    - b. cornifying.
    - c. hyaline.
  - 2. Paraplasmic.*
    - a. fatty.
    - b. pigmentary.
    - c. mucoid.
    - d. colloid, etc.
  - 3. Nuclear (? increase of chromatine).

We begin, therefore, with necrobiosis. We may appropriately mention first those organs of which the existence is limited in time, such as the thymus and the fœtal kidney (mesonephros or Wolffian body). These organs attain first their full differentiation; their elements during the next phase die off, and finally are resorbed, most of the organ disappearing. In the same category of change belong the histories of the senile ovary and testis. Another familiar illustration is offered by the notochord, which in the mammals totally disappears during the fœtal period. The notochord cells undergo peculiar characteristic modifications, hence it is difficult to say whether or not there is degeneration in the strict sense. Cell-death on a large scale is a common phenomenon of the tissues. It occurs in cartilage both when the cartilage is permanent and even more conspicuously when cartilage gives way to bone, the disintegration of the cartilage cells preceding the irruption of the bone forming tissues. It occurs among the bone cells after they are imbedded in their calcified matrix. It occurs in the ovary, where we designate its result as atresia of the follicles. It occurs in the sebaceous glands as an accompaniment of the process of their secretion. It occurs among the glands of the intestine as discovered by Stöhr, and occurs normally, though not constantly, in the appendix, as recorded by Ribbert. It occurs in the epithelium of the human pregnant uterus and in all the tissues of the human decidua reflexa. Other examples could be enumerated, but we may content ourselves with citing the constant destruction of blood corpuscles, both red and white.

Degeneration, in the stricter sense of an ante-mortem hypertrophic change of cell structure, is also of widespread occurrence in the healthy body. No case of so-called granular degeneration under strictly normal conditions is known to me, though it seems quite credible that such cases should occur. On the other hand, the cornifying degeneration is very important and does occur in all three germ-layers, for we observe it in the ectoderm of the skin, the entoderm of the œsophagus and the mesoderm of the vagina. Hyaline degeneration of so striking a character as to have been termed pseudo-pathologicial takes place regularly in the ectoderm (outer epithelium) of the placental chorion. In the rabbit it occurs in the uterine glands, during pregnancy, causing most rapid histolysis, and it seems to me probable that some of the changes, which can be observed in the decidua of the pregnant human uterus

* I cannot venture to assert that these two divisions are valid, and not arbitrary.

ought also to be regarded as cases of hyaline degeneration. That fatty degeneration takes place normally has long been taught. There seems no reason for regarding the development of ordinary or mesenchymal fat-cells otherwise than as instances of normal degeneration. In old age a more or less marked fatty degeneration may be wide spread and occur in many different kinds of cells. The same is true of the deposit of pigment, as we see it in the liver cells and motor nerve cells of adults. Finally, mucoid and colloid degeneration are so obviously normal, that we commonly think of their pathological occurrence as merely an exaggeration of a normal state.

The various kinds of changes in dying cells, with which the pathologist is most familiar, recur in healthy tissues. In the preceding table seven forms of change are enumerated under the heading '*necrobiosis.*' Every one of these seven occurs normally. Granulation of the bodies of the cartilage cells and of the notochord cells may be observed to precede their resorption. Hyaline transformation is conspicuous in the decidua reflexa. Imbibition or cellular œdema occurs in the epidermis of the lips, in the cells of the uterine glands during pregnancy after they have detached themselves from the gland walls, and in the endothelium of placental blood vessels of the rabbit. Desiccation is the usual accompaniment of cornification. Clasmatosis has given its name to the clasmatocytes of Ranvier, and we may well apply the same term to the cells of the secreting milk gland, and also, as an unpublished research indicates, to the cells of the secreting glands of the cervix uteri. Karyolysis is, according to present probabilities, the method by which nucleated red blood cells are converted into non-nucleated blood-corpuscles. Karyorhexis, or the fragmentation of the nucleus, occurs in the cells of the disappearing follicles of the ovary.

Lastly as to the removal of cells. The sloughing off of cells is one of the most familiar phenomena, since it occurs incessantly over the epidermis and with the hairs; its part in menstruation and its colossal rôle in the afterbirth are known to all, and every practitioner is accustomed to look for shed cells in urinary sediment. Large numbers of cells are lost by the intestinal epithelium. Cells without access to the external world must be got rid of by resorption, which seems to take place either with or without the cooperation of leucocytes. In the latter case we must for lack of a better hypothesis attribute the resorption to chemical means. Of resorption with the aid of leucocytes the necrosed human decidua reflexa offers a perfect illustration. Of resorption without leucocytes the masses of degenerated epithelium in the placenta, periplacenta and obplacenta of the rabbit afford by far the most impressive demonstration I have ever seen. At nine days after conception the epithelium is profoundly changed, being very much thickened, and where thickened transformed into a syncytium without cell boundaries, but with an enormously increased number of nuclei. In the obplacenta (or portion of the uterine wall opposite the placenta proper) portions of the epithelium from the fundus of the glands remain, but the upper stratum has not only undergone syncytial degeneration, but has become vacuolated and partly resorbed without being directly attacked by either leucocytes or epithelium or any other kind of cells. At eleven days the resorption has progressed still farther, so that the degenerated part is almost gone, but meanwhile the isolated patches of epithelium have spread until they have united and so reformed a continuous epithelium. At thirteen days the epithelium has reconstituted new glands or follicles, very unlike, however, those of the resting uterus. To ex-

plain the extraordinarily rapid disappearance of the degenerated material in the obplacenta the only available hypothesis seems to be that of a chemical change by which the material becomes soluble or is dissolved, for we see the disappearance of the substance taking place in the very heart of the layer, and not merely at the surface. Sloughing is impossible and there are no phagocytes, leaving the chemical explanation as the only one I have been able to conceive. The contemplation of the described phenomena of the rabbit's obplacenta inevitably raises the question—do we not tend in our explanations of the removal of necrosed and degenerated tissues to attribute too much to phagocytes and too little to direct chemical action? May it not be that the body produces histolytic toxins, which can destroy tissues somewhat as do snake-poisons?

The cycle of changes through which cells pass is obviously longer than the period of development and the differentiation, yet its phases all belong together as members of a single series. We lack a word to designate the entire series of changes, and for the lack of such a word often fail to appreciate the essential unity of progressive and regressive modification of cell-structure. Accordingly, I wish to propose the new term *cytomorphosis* to designate comprehensively all the structural alterations which cells, or successive generations of cells, may undergo from the earliest undifferentiated stage to their final destruction.

PART II. PATHOLOGICAL DIFFERENTIATION.

We have now completed our brief reviews of the four fundamental successive stages of cytomorphosis. These stages are:

First .Undifferentiated.

Second. Progressive differentiation, which itself often comprises many successive stages.

Third. Regression (necrobiosis or degeneration).

Fourth. Removal of the dead material.

Let us now apply some of the conceptions won to the interpretation of pathological differentiation, remembering all the time that the interpretation of disease is a distinct and different problem. Although presumably pathological differentiation is the sole and exclusive cause of disease and no disease arises from any other immediate cause, yet the disease must be regarded as the result and, owing to the physiological correlation of the organs, this result may include many secondary effects, some of which are often of the greatest diagnostic value, and therefore likely to divert attention from the primary structural cause.

Our review of normal conditions furnishes us with three general conceptions, which are valuable for their pathological applications,—namely:

First. That each germ layer has a specific and exclusive share in the production of tissues.

Second. That undifferentiated cells, characterized by having only a small amount of unspecialized protoplasm, exist not only in the embryo, but also throughout life in certain parts of all three germ-layers.

Third. That differentiated cells characterized by having a larger amount of specialized protoplasm, form most of the organs of the adult and are incapable of undergoing any new unlike differentiation, though they are still capable of completing their cytomorphosis, by necrobiosis or degeneration.

We must apply these conceptions, according to my belief, as rigidly to pathological as to normal development. Thus, as to the germ-layers, it ought to be possible even with our present knowledge, to show their pathogenetic values, so that every elementary student as a matter of course can be taught to classify accurately most pathological differentiations, and to accept such

a classification as the basis of all his further study of the science. How much this reform is needed is indicated by the many writers who put glioma under the head of connective tissue tumors, although gliomata arise from the ectoderm, and connective tissue arises from the mesoderm. Such a classification is on a par with the ancient system which put the whales among the fish, for it is not going too far to say that it is impossible that connective tissue should produce a glioma, because the two things belong in different classes. Another noteworthy violation of embryological law is offered by the classification of all muscle-tumors under one head, '*myoma*,' although smooth and striated muscle fibers are genetically and structurally distinct, with no intermediate or connecting forms of tissue, and with only a slight physiological resemblance. As regards epitheliomata; they should be studied in relation to their layership, and it is reasonable, in my judgment, to expect that they will be found to have very distinctive characteristics according to the germ-layer from which they take origin, for the layership of a tissue governs the normal differentiation and therefore probably also the abnormal. I believe that the first competent investigation in this field will mark a new epoch of pathological science. When the epoch comes our morphological sense will no longer be shocked, as for instance by the application of the name adenoma to an epithelioma of an organ like the kidney, which is in no sense a gland.

I should like to urge especially the study of the layership of the various cancers. Can we safely assume that there is only one kind of cancer? May it not well be that ectodermal, mesothelial and entodermal cancers are separate kinds?

Next as to undifferentiated cells. The cells of this sort have the power of multiplication in a high degree, and they have the possibilities of increasing their size and of undergoing further differentiation, and their occurrence in the adult is of the utmost pathological significance. Such cells exist in four important parts, (1) in the basal layer of the epidermis and in corresponding portions of the epidermal appendages; (2) in the adult mesenchyma or connective tissue; (3) in many parts of the adult mesothelium, especially of the epithelia of the genito-urinary tracts; (4) in the entodermal epithelium of the gastro-intestinal tract. It is significant that it is precisely from these parts that the development of many rapidly growing tumors takes place, and it is further significant that the least differentiated or specialized of all, namely, the mesenchymal cells, are the ones which produce the greatest variety of tumors—as the following list recalls: myxoma, myoma (but not rhabdomyoma), fibroma, lipoma, chondroma, osteoma and sarcoma. Angioma presumably belongs in a different category. The mesenchyma still exhibits, by the formation of its characteristic tumors in the adult, its embryonic capacity to transform itself in varied ways.

Further insight into pathological development may be gained from the tissues or cells which have undergone differentiation, but do not attain a high grade of specialization. The endothelium of blood-vessels, the endothelium of lymph-vessels, the red-blood cells, the leucocytes and the neuroglia are examples of this class. All the cells of the kind just enumerated have advanced in organization beyond the embryonic state, but have retained the power of cell multiplication. When they multiply they produce cells like themselves, so that we might describe them as so many histological species each capable of reproducing its own kind. In accordance with this conception, derived from the normal development, is the pathological fact that each of these

species of cells produces tumors of its own kind. This is a familiar conclusion as regards the endothelium, both of the blood-vessels and of the lymph-vessels, and also as regards the neuroglia. It seems to me that the excessive multiplication of leucocytes may properly be classed in the same category as the growths resulting in angioma and glioma. I do not know whether or not an excessive and abnormally rapid production of red blood cells may occur so as to occasion a special and distinct disease. Increased production of red blood cells (erythrocytes) is, of course, well known to occur, but I understand that a distinct disease of this origin is, as yet at least, not recognized. It is not improbable, however, that such a disease exists—we should, I suppose, name it *erythrocytosis* or *haematoma*.

We can now distinguish two main groups of new formations; first, those with marked cytomorphosis, or changes in cell structure, as, for example, myoma, lipoma, chondroma, etc.; second, those without marked cytomorphosis, the cells of the new growth resembling those of the parent tissue as, for example, angioma and glioma.

Members of the first group have been termed *heteroplastic*.

Members of the second group have been termed *homoplastic*.

Accepting these terms, we may say tumors are either *heteroplastic* or *homoplastic*. From the standpoint of the embryologist these terms are much more than convenient adjectives; on the contrary, they denote differences of a fundamental character, upon which we must base a large part of our notions about pathological differentiation.

Finally, as to the differentiated cells. We have just considered cells which have reached a low degree of differentiation, and therefore will now give our attention only to the most highly differentiated. Of these the nerve cells, or as they are now termed, the neurones, stand highest and are characterized not only by the great specialization of their organization, but also by the complete loss of their ability to multiply by cell-division. The neurones are then extremely unlike the embryonic cells and they represent the extreme end of that scale of which the undifferentiated cell is the beginning. It is, therefore, very significant that neurones do not form tumors. Neuronoma, as such a tumor would be called, does not occur, so far as hitherto recorded—and if, as is possible, a neuronoma should be found, we should have to explain it not as a tumor-growth of neurones, but as the result of proliferation of indifferent cells, which subsequently became differentiated into neurones. The so-called neuromata of pathologists do not here come into consideration because they are merely accumulations of growing axis-cylinders.

Liver cells and striated muscles also represent a very high differentiation. It is possible that with more exact knowledge we shall be able to state that these elements also cannot produce tumors, although there may be tumors of the liver and of striated muscle-fibers. Possible, because Cohnheim's famous theory of tumor origin from persistent embryonic tissue may be, though not generally applicable, available in these two instances. The adoption of this view would furnish an explanation of several familiar facts; of the fact that we do not find tumors formed by differentiated liver cells; of the fact that cancer of the liver arises usually from the bile-ducts, which have a simple and little differentiated epithelium; of the fact that myoma of the cardiac and of the developed skeletal muscles is exceedingly rare; of the fact that rhabdomyomas so occur that their origin may be attributed to inclusions of portions of embryonic muscle plates. As regards primary epithelioma of the liver, it is claimed that it arises usually from the bile-

ducts, but the liver-cells are also involved, but how it comes about that the liver-cells participate is, so far as I have been able to learn, by no means clear. From analogy with other tissues, we infer that it is improbable that the large and specialized liver-cells ever resume an embryonic character. In short, I deem our understanding of the pathological differentiation of hepatic cells and of striated muscle fibers too imperfect to support a judgment. We can only say that the rarity of such differentiation concords with the degree of normal specialization of the cells and fibers in question.

Our very brief discussion of pathological differentiation seems to justify the following conclusions: *First*, the process in its essential features is identical with the process of normal differentiation; *second*, the character of a tumor depends primarily upon the layership of the cells producing it; *third*, normal differentiation impedes and limits the formation of tumors, precisely as it does of further normal structures; so that tumors arise most readily from undifferentiated tissues and may then be heteroplastic; and arise readily from differentiated tissues and are then always homoplastic; and arise unreadily or not at all from the most highly specialized tissues.

Each of these three conclusions might be advanced as a law of normal development, if we substitute the term 'differentiated tissue' for 'tumor.'

We now pass on to the final stage of cytomorphosis, necrobiosis and hypertrophic degeneration in their pathological manifestations. The consideration of the direct or simple death of cells need not detain us, nor need we pause long over the indirect forms of cell death. In fact, the analysis made earlier this evening of normal necrobiosis and degeneration forced us to recognize that all, or nearly all, the modes of indirect cell death which the pathologist encounters in morbid tissue recur under healthy normal conditions. To put the conclusion in its correct form, we need only to reverse it, saying:

Most, and probably all, pathological necrobiosis and degenerations of cells are essentially identical with normal processes, and are pathological, owing to the abnormality of their occurrence in time and site.

Death of a cell may, of course, occur at any moment as a consequence of conditions external to itself. To a given cell, as such, it is of no moment whether the term 'physiological' or 'pathological' be applied by us to the conditions which cause its death. The cell has its own inherent qualities, and its own cytomorphic possibilities. All that the environment of the cell can do, so far as we can at present understand, is to evoke, and perhaps to a minor degree modify, one of the possible structural changes of the cell. Hence we find actually that the processes of cellular necrobiosis appear to us identical in normal and pathological cases. This affirmation does not imply that a given cell has only one kind of possible necrobiosis before it. Quite otherwise, it being reasonable to believe that any one of several forms of necrobiosis, according to the circumstances, may ensue.

All that has just been said might be repeated in reference to hypertrophic degeneration. One of the investigations which is most needed at the present time, and which promises results of extreme interest and importance, is the investigation of necrobiotic and degenerative cytomorphosis, carried out as a research upon cell structure. At present we cannot discuss the subject except in terms the very vagueness of which is a mortifying confession of ignorance.

Time forbids the prolongation of the discussion. But, although a more detailed study is thus for the present excluded, we

have, nevertheless, dealt with the subject with sufficient fullness, I hope, to convince you, if you were not already convinced, that the fundamental problems of pathology and embryology are alike, not only in being problems of cell life, but also in being similar and even identical problems of cell life. Widely as the two sciences differ, they rest on a common foundation.

To complete our subject it would be necessary to summarize our present knowledge as to the causes of cell differentiation. Physiological morphology is a new science; we have barely crossed its threshhold, and are not yet at home in it. To the physician this new science promises to far surpass in practical importance even the bacteriology of our time, since it is not presumptuous to hope that when we understand the physiological factors, thermal, chemical stimulant, mechanical and other, which bring about structure, which cause cytomorphosis, we can acquire control over cellular differentiation, and ultimately be able to prevent some of the most formidable diseases, over which we now have little or no power. The diseases which we may attack in the future in this way are diseases which may be designated as morphogenetic, because they are due to errors of morphological differentiation. At this vast topic it is impossible now to more than hint.

Here we may stop, not because all the great host of relations between embryology and pathology have been marshaled before us, but because enough of these relations have passed us in review to present a conclusive body of arguments. As we follow their march, we find ourselves led to the attack upon the problem of the causes of the specialization of cells, of histogenesis. To conquer this problem our only hope lies in the junction of all our forces.

Before closing, a personal word: first, of sincere thanks for the honor you have conferred upon me both by your invitation and by your attention, and then a word to express the great diffidence with which I have undertaken to deal with pathological phenomena. A man of science ranks according to the number of details which he has mastered, and his ability to drill them into coherent battalions. By no such system of ranking can I hope to be included among pathologists. I offer, therefore, only the thoughts of an outsider, derived from the long pursuit of a cognate science. Such external suggestions, being independent to some degree of pathological tradition, may contribute to vivify the conception of the unity of the biological phenomena and, therefore, of all forms of biological investigation. It will be a service rendered if my words recall the great truth that biology is not a congery of sciences, but a single science, which we artificially divide and subdivide until the parts are commensurate with our mental capacity. In the truest sense we are fellow-workers. Let us, therefore, work together.

CHARLES SEDGWICK MINOT.

THE DETERMINATION OF THE TYPE IN COMPOSITE GENERA OF ANIMALS AND PLANTS.

To the older naturalists a genus was a subdivision of an order containing a number of species, each standing in like relations to the genus. The genus was a pigeon-hole into which species of similar characters were thrust.

In the modern conception a genus is a group of related species, associated about a single one which is the type of the genus. In theory this type should be the central species or the most primitive one. In the exigencies of nomenclature, it is the one which was in point of fact first associated with the generic name. Modern writers recognize this grouping of species about the generic type, and to each new genus of

most recent writers a type is definitely assigned by the author of the genus. In modern rules of nomenclature the definition of a genus may be altered or even reversed, but the generic name must adhere to the original type.

The most serious difficulty in connection with the matter of nomenclature lies in the reduction of the ancient conception of the genus to the terms of the modern one. It lies in the assignment of a type species to a group in which the original author had no conception of the need of such a species.

In the subdivision and fixation of the ancient genera, various methods have been followed, with varying results. In other words, these methods have lacked the one important element of inevitableness. A rule of nomenclature has little value unless it lies in the nature of things. If it is artificial, it will be discarded.

In general, three methods have been followed in fixing the types of the early composite genera:

1. To follow the arrangement of the author who first subdivides the genus subsequent to the work of the original author.

In this many difficulties have been found in practise. The first restriction is often in obscure publications. It is often obscurely done. In other words, a genus is often subdivided in such a way as to leave no clear idea as to what the author would leave in the original group. Sometimes he leaves nothing at all, as in the case of the Linnæan genus, *Sparus*, for which no place was left after its subdivision. As a matter of fact, this system leaves the proper application of many generic names in doubt, and necessitates a profitless investigation of the opinions of early authors who wished to improve Linnæan nomenclature, but who worked on too small a scale to accomplish much.

A second system derived from this is the method of elimination. The genus of the eighteenth century corresponds roughly to the family of the nineteenth. The family may contain several genera. These may be withdrawn from the original genus in chronological order, and the old name left with the final residue. But this residue will generally consist of foreign species or species unidentified or unidentifiable. To meet this difficulty the method of elimination in birds has been applied to European species only, that generic names based primarily on European forms may not be forced out of the European fauna. To make the system workable a variety of other minor rules must be invented, as a little change in the point of view as to some obscure author will make an entire change in the final result. The final result is the only matter of interest.

The ornithologists have found this scheme workable and it is incorporated in the rules of the American Ornithologists' Union. But even here it has not yielded stability of nomenclature, as several generic names (as of owls, loons) have been more than once altered in obedience to its dictates. But in American ornithology any rule has the great advantage of the imposition of authority. The ornithologists of America agree to stand by their committees, and any decision these may make is final for them and their associates, that is for most ornithological work in America for the present generation.

Other branches of science have no such authority behind their verdicts, and without it the determination of generic types by elimination is a failure. Often two men working independently cannot reach by the same rules an identical result. It is not always easy for the same man to reach the same result twice.

Let us take a concrete problem. The genus *Clupanodon* of Lacépède (1802) containing those herrings which have no teeth includes several modern genera.

It was based originally on six species, *thrissa, nasica, pilchardus, sinensis, africanus, jussieu.*

In 1810, Rafinesque proposed to substitute *Thrissa* for *Clupanodon,* presumably because the latter name is badly formed. Presumably again, *thrissa* would be the type of this genus of Rafinesque, who again presumably took it, as the first species mentioned, as the type of *Clupanodon.*

In 1820, Rafinesque founded the American genus, *Dorosoma* (Chatoëssus), and to this genus *nasicus,* and afterwards *thrissa* were referred; *pilchardus* was long left in *Clupea,* which is older than *Clupanodon,* but in 1860 a related species (*pseudohispanicus*) became the type of the genus *Sardinia* of Poey. *Africanus* has teeth and does not conform to the definition of *Clupanodon.* It was made, in 1839, the type of a genus *Platygaster,* Swainson, but this name is preoccupied. Afterwards *Ilisha* (Gray, 1846) and *Pellona* (Valenciennes, 1847) were based on a species of the same type, the former without definition. *Sinensis* and *jussieu* were placed, in 1847, in a genus *Clupeonia,* by Valenciennes. Finally in 1900, Jordan and Snyder established the genus *Konosirus* on a Japanese species (*punctatus*) which proves identical with *thrissa,* and to which group *nasicus* also belongs.

In their first consideration of this generic name, Jordan and Gilbert succeeded in convincing themselves that *Clupanodon* should take the place of *Clupeonia.* Eliminating *Pellona,* and the earlier names *Dorosoma* and *Clupea, Clupanodon* was left for the remaining species, *sinensis* and *jussieu.*

But in 1896, Jordan and Evermann recognized that if *Sardinia* were a distinct genus, the rule of elimination required them to transfer to it the name *Clupanodon,* as *Sardinia* is of later date than *Clupeonia.*

In 1900, Jordan and Snyder showed that *Dorosoma punctatus* was the type of a distinct genus, which they called *Konosirus.* Later it became evident that *thrissa* was identical with *punctatus* and by the law of elimination the name *Clupanodon* must supersede *Konosirus* as *thrissa* was the last of its species to be removed to a genus of its own. By this system the old generic name can never come to rest, but must be held in readiness to replace any new genus which may be formed from species included in its original content.

It was possible to defend in turn the use of *Clupanodon* in place of *Clupeonia, Sardinia,* and *Konosirus.* Should *nasica* ever receive a distinct generic name, *Clupanodon* must again move forward to replace it. On the other hand, writers called 'conservative' will reunite *Konosirus* with *Dorosoma* and *Sardinia* and *Clupeonia* with *Clupea.* In such case *Clupeonia* must fall back on *Ilisha,* a group originally included in *Clupanodon* by error. It is evident, that in this case no fixity is possible by the method of elimination, unless imposed by the temporary authority of some ichthyological union or mutual agreement among writers.

In default of such the present writer will use *Clupanodon* in place of his own genus, *Konosirus,* not on account of the results of elimination, but because the type of *Konosirus* is the first species named by Lacépède under his account of *Clupanodon.* If he should grow more 'conservative' he might reunite *Clupanodon* with *Dorosoma.* In such case he would call the whole genus, *Clupanodon,* because the name is prior to *Dorosoma.*

The third method of determination of generic type is through consideration of the work of the author of the genus in question, without regard to the views or work of any subsequent matter.

This we do in accepting as the type of a genus the species indicated as such by the author. Such a statement cannot be reversed by any later author. In recent days, the type of a genus usually is indicated once for all in so many words. With earlier

writers who did not take this method we may be allowed to read between the lines. A leading ornithologist (Alfred Newton, if I am not mistaken), suggests that in the case of Linnæus we be allowed to ask the author what type he would have chosen if the modern problem were to be presented to him. As to this we should not be often left in doubt. If we are in doubt however, there is a very simple rule followed widely by naturalists, notably by Bleeker, the most voluminous writer on fishes. This is the selection, as type, of the first species named under the genus by its author, when other indications fail. This rule gives fixity, the sole essential thing. It gives justice. It saves a profitless overhauling of bibliography, and it is a clear way out of confusion. It is the only possible clear way.

I suggest for consideration the following provisional rules for the application of this method:

1. The type of a genus is the species designated as such by its author.

2. If no type is designated by the author, either explicitly or by clear implication, then the first species referred to the genus or the species standing first on the page, shall be considered as its type. A generic name should have no standing, if resting on definition alone, nor until associated with some definite species.

3. To this rule the following provisional exceptions may be made. The type of each genus of Linnæus as stated by him is 'the best known European or officinal species' it contains. In case of doubt in the application of this rule, the species standing first may have the benefit of the doubt. Unlike most subsequent authors, Linnæus usually placed his type species near the middle in the list of species. Cuvier made it his 'chef de file.'

4. In case of genera based on old specific names (*Belone*, *Achirus*, *Trachurus*) the species thus furnishing the name, if actually mentioned by the author of the genus, may be regarded as its type.

5. Possibly, to avoid confusion, it may be well to retain old generic names, restricted by common consent to a species not the first mentioned by the author, provided that such restriction antedates any modern names for the same genus. Thus it may be well to retain *Centropomus* for *Oxylabrax*, instead of *Lucioperca*, *Cheilodipterus* for *Paramia*, instead of *Pomatomus*, *Pomacanthus*, for *Pomacanthodes*, instead of *Zanclus*. But I doubt the wisdom of this exception, and I shall not be surprised to see future writers following Bleeker in the use of *Oxylabrax* and *Paramia*, leaving the generic names of Lacépède and of all writers since Linnæus, to the first species named by their author.

DAVID STARR JORDAN.

---

*NOTE ON THE NUMBER OF PARTICLES IN THE SATURATED PHOSPHORUS EMANATION.**

IN a series of experiments made by passing air ionized to saturation by phosphorus through a slender tubular condenser (60 cm. long, radii of air space, .30 cm. and .16 cm.), I showed that the electrical current radially through the condenser for a given potential difference, and the volume per minute of the ionized air sent longitudinally through it, were rigorously proportional quantities. At the same time the color of the steam tube observed on passing the air from the condenser into it, was invariable no matter whether the condenser was charged or not, *cæt. par.* Hence only an insignificant part of the particles producing condensation takes part in the electric current even with radial fields of 2,100 volts per cm., the highest safely admissible. I have estimated that less than 5 per cent. of

* Preceding experiments in SCIENCE, Feb. 9, 1900, the above note being a sequel. I there gave relative values for the absorption velocities, absolute values being given in the *Am. Journ. of Science*, March, 1900.

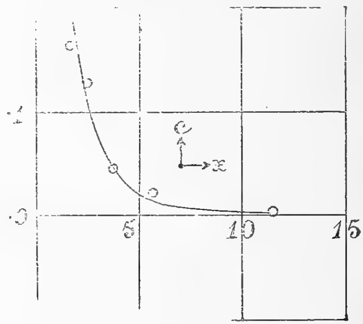
the ions could have been destroyed by the electric transfer; otherwise the steam tube would have shown perceptible variation of color.

In connection with this result I have questioned whether the importance of the mutual destruction or decay of the ions has not been overestimated; whether the phenomenon of leakage in a plate condenser may not be very fully explained* by taking account of the ions which wander *laterally* out of the field of force. Let A be the area of the condenser of air space x, and let ax be the circumferential area terminating in the edges of the condenser (mantel of the cylinder of air). If one of the plates is a phosphorus grid (thin pellets of phosphorus secured between appressed discs of wire gauze), let n be the number of particles per cubic centimeter at a normal distance x from the grid. Let k be the (absorption) velocity of the ions in the absence of an electrical field when passing from a saturated region either into free air or normally to an absorbing surface, and $k'n^2$ the number decaying per cubic centimeter per second.

Remembering that in such a condenser there is lateral loss of ions escaping from between the plates, as well as the loss upon the plates whether the (phosphorus) condenser be charged electrically or not, the differential equation meeting the case is $-dn/dx = n(a/A + nk'/k)$. This is integrable in finite form, and if n_0 be the number of ions per cubic centimeter at the phosphorus plate (saturation), the equation becomes $n/n_0 = (a/A)/((a/A + n_0k'/k)\varepsilon^{(a/A)x} - n_0k'/k)$. If $k' = 0$, decay within the ionized space is ignored and $n = n_0/\varepsilon^{ax/A}$. Thus n is independent of the absorption velocity k, depending for a given initial saturation n_0 only upon the mantel (ax) and the base (A) areas of the condenser air space.

Now let the condenser be charged, remembering that the additional loss from this cause alone is insignificant. Let V be the potential difference at the time t, C the effective capacity, U the relative or mutual velocity of the ions, e the charge of each. Then $-dV/dt = AUVne/Cx$, or from the value of n, $-dV/dt = (AUVn_0e/C)/x\varepsilon^{ax/A}$.

In my data given in the *Physical Review* (l. c., Table III.) I put, as usual for leakages, $V = V_0 10^{-ct}$, whence c was computed. Substituting this in the preceding equation, it reduces to $c = (AUn_0e/Cln10)(1/x\varepsilon^{ax/A})$.



In the annexed diagram I have drawn this curve and distributed the observations with reference to it by so determining the constant $AUn_0e/Cln10$, that the first observations coincide ($c = .200$, $x = 1.7$). The agreement of the theoretical curve and the observations is so striking as to give great probability to the hypothesis that decay* is here relatively insignificant.

It is even possible to make an approach toward computing the constant, which since c in my observations is taken rela-

*See my paper in the *Physical Review*, X., p. 257, 1900, whence the data of this paper are taken.

*How much importance is to be attached to this decay (k') I shall show in experiments with spherical condensers in which the ions can not escape. These results, while giving no evidence of decay, show that dilution (since saturation must fall off at increasing distances from a central phosphorus emanator) is accompanied by additional ionization; *i. e.*, there is relatively too much current, *cæt. par.*, when the spherical condenser is larger.

tive to minutes instead of seconds, now becomes $K = 26AUn_0e/C$. For if the velocity of the ions produced by phosphorus is like that of other gaseous ions, U is of the order (say) of 1 cm./sec (Rutherford, Townsend, Chattock) and e of the order of 7×10^{-10} electrostatic units or 2.4×10^{-19} coulombs. The ratio of areas in my condenser was .35, the area $A = 132$ cm^2., the capacity C about 90 cm. or 10^{-10} farads. Finally the observed value of K as used in computing the above curve was $K = .634$. Thus the initial saturation $n_0 = .634 \times 10^{-10}/26 \times 132 \times 1 \times 2.4 \times 10^{-19} = 8 \times 10^4$ nearly. Hence if all the ions which reach and are absorbed by the condenser plates actually convey electric charge, less than $n_0 = 10$ ions per cubic centimeter occur in the saturated emanation contiguous to the surface of the phosphorus grid.

If now, instead of $U = 1$ cm./sec. for the field of a volt per centimeter, the absorption velocity $k = .3$ cm./sec. found in the absence of an electric field (*Am. Journ.*, March), were taken, the number n_0 would be about 3 times larger; in such a case a special mechanism of electrolysis, as I endeavored to sketch it elsewhere, is in question. What I wish chiefly to point out, however, is that the order of the velocities U and k, obtained from such widely different experiments, is about the same. Indeed if one supposes that but 1/3 of all the ions travel in a given cardinal direction, $3k$ will replace k in the above estimates, and the close proximity of $3k$ and U is even more striking.

BROWN UNIVERSITY, Providence, R. I.

SCIENTIFIC BOOKS.

Report of the U. S. Commissioner of Patents to Congress for the year ending December 31, 1900. Washington, Government Printing Office. 8vo. 1901. Pp. 19.

Among the many causes which have conspired to give the United States its present leading position in the industrial world, it may be doubted whether any single influence has been more potent than that liberal system of patent law which was established in the days of Washington and Hamilton, and which has been constantly under revision, usually and until lately with improvement, throughout the century. That defect which permits the inventor to secure a patent upon the simple presentation of a written claim, with a drawing or a diagram, and without any real work in successful reduction of the scheme to practise, and that which allows the inventor to secure indefinite retention of his legal claim—by the equally simple expedient of so wording his claims that the examiner will be sure to object, taking two years to frame another objectional claim, repeating this process, until the time is ripe for gathering in a profit—will be remedied whenever the committees of Congress choose. The few defects in the existing system are capable of instant remedy and its excellent features far outweigh its faults. That the Congress, the Commissioner, the public and especially the patent attorneys permit defects to remain is unfortunate; but it remains nevertheless the fact that we have the best system of patent-law yet produced and that it has done much and is still doing much to stimulate invention, to promote the efficiency of manufactures and to give prosperity to the country and to its average citizen. No more important duty lies with the legislative branch of the Government than that of sustaining and perfecting this code.

The Commissioner reports annually to the Congress. In the report before us he states the total receipts for the year 1900 at \$1,350,828.53, the expenditures \$1,260,019.62 and the profits for the year as the balance, \$90,808.91.

The Patent Office has always made a profit on its business with the usually poor inventor, and this extortion of money from the greatest benefactor which this country knows in industrial fields has permitted the accumulation of an enormous sum, now reported by the Commissioner as \$5,177,458.55 in the United States Treasury, standing at that figure on the books of the Treasurer to-day. In other words, the poor inventor has contributed not only thousands of millions to the wealth of the nation,

and placed the United States in the forefront of nations; but he has been compelled to spend practically all that he has received, in the average case, in the introduction of his invention —for the average inventor lives and dies poor, spending every dollar he can earn or borrow in promotion of his ideas and inventions—and he has, meantime, contributed over five millions of dollars to the treasury of the wealthiest nation on earth while giving that nation's inconceivable advantage and position.*

It would seem that the inventor may well claim that he is treated with unconscionable inequity and ingratitude; but the depth of that inequity and ingratitude is not yet sounded. He has deposited in the United States Treasury, out of a painfully-earned pittance, in the course of a century, in the small contributions made by thousands of patentees, $5,000,000; which sum is definitely pledged by the nation to the purposes of the Patent Office and of the inventor for whose benefit it is in part established. Meantime, the Patent Office has been for years painfully crowded, its work seriously impeded and its employees have suffered, as well as the inventor and the industries of the country, through lack of proper provision for its work and of suitable space for its collections, papers and models, and its library, all of which are in constant danger from fire. Other divisions of the Department of the Interior have been for years past squatting in its territory and occupying valuable and needed space, belonging to the Patent Office and in its own building, while five millions of dollars belonging to it and the inventor are hoarded in the United States Treasury with its hundreds of millions surplus, and its use withheld either for constructing a new and suitable fire proof building —the proper course—or for relieving the existing embarrassment in other ways. Truly 'Republics are ungrateful'!

During the year 1900, over forty thousand patents were applied for and nearly six thousands caveats, trade-marks and designs. Twenty-six thousand patents were issued and twenty-one thousand expired. New York heads the list with 3,788 patents and Pennsylvania and Illinois follow with 2,564 and 2,439; but Connecticut leads in inventiveness; securing one patent to every 1,203 inhabitants; although the District of Columbia is reported to have one to each 1,110. The latter is of course not precisely comparable with the States; the patents being often taken out by immigrants, coming to the capital for the purpose, or by residents uniting with the inventor in application for the patent. About one in 1,500 New Englanders takes out a patent each year. The average for the country is about one patent in the year for each four thousand inhabitants. The 'Yankee' is about twenty times as inventive as the South Carolinian. Women have about one patent in each 1,000. The number of patents issued has of late years been nearly stationary at about 22,000; growth having apparently practically ceased about fifteen years ago.

Inventors complain that the law and the administration, and especially the courts, have recently often been inclined to bear hardly upon the man who provides the people with their main instrument of prosperity. Certain States are well known among patentees as dangerous, through their adverse court-decisions, and the United States District Courts and even the Supreme Court of the United States are sometimes thought too indifferent to the rights of the inventor and of the people in this direction. It is, however, hardly possible for a court to invariably exhibit the knowledge or the judgment of the expert in the field of mechanics, and the famous decision of the latter court, when it was decided in the great Sickels-Corliss case that a latch is not a catch and that a dash-pot and another dash-pot are not equivalent, must be expected to be occasionally paralleled. Something should be done, however, to restore to the inventor that consideration which was formerly his and which has of late been in some degree lost to him, in part perhaps, through familiarity with his work and through the very extent and universality of his beneficence.

As to the standing wrong—refusal to prevent

* This reminds one of the action of a Legislature of the State of New York which compelled Ezra Cornell to pay $25,000 for the privilege of endowing the Land-Grant College of that State with $500,000 and 200 acres of land to be succeeded later by millions of dollars from Cornell, Sage, Sibley, White and others.

the use of his own funds for the construction of a suitable government building for his benefit, in which fire-proof construction shall insure the safety of invaluable records and where ample space and every convenience shall insure prompt attention to his business—the senior senator from Virginia has recently admirably stated the case :

"Other nations have surpassed us in literature and the fine arts, but in inventive and useful arts the United States is far transcendent. The Patent Office, established by Thomas Jefferson and protecting for a brief period the only constitutional monopoly, the right to the exclusive enjoyment of one's original ideas, is the crown of American intellectual supremacy over the material world, even as the Constitution of the United States is the crown of political architecture and the Union itself the crowning glory of our people.

"As Francis Bacon says, 'The sciences dwell sociably together,' and we should put on Capitol Hill, facing the Senate Hall, as a companion piece to the exquisite Library building now facing the Hall of Representatives, another building of like architecture. And the American capitol of letters should have by its side the American capitol of inventive art, both facing the Capitol of the people, where their sovereignty has its highest exemplification. In that hall should be displayed the evolutions of inventions, with every invention indicated by its model, inclusive of the last improvement. It would be the greatest college of applied science that the world has ever seen ; a monument to and a stimulus to invention, and leading by gradations to those truths of science which hover over the threshold of the age, 'waiting to be caught.'"

R. H. THURSTON.

Photographic Optics. By OTTO LUMMER, Professor, Assistant in the Reichsanstalt, Berlin ; translated by Professor S. P. THOMPSON, London, Macmillan & Co.

A very complete and concise treatment of the theory of the modern photographic objective, with a full exposition of von Seidel's theory of aberration. The subject as a whole is rather deep for the general reader, though portions of the book cannot but help interest any who desire to know more about the various modern objectives ; though they may not be able to penetrate the mysteries of the five different kinds of spherical aberration, and two chromatic aberrations which are taken into account in the computation of the complicated optical systems in use at the present time, they will find much of interest. A perusal of the book will at least give the photographer a respect for, and appreciation of his instrument far greater than can be had by the inspection of a few negatives and a glance at the optician's bill. A photographer should at least know as much about his lenses as an engineer knows about his engine, and yet how few can tell why the stop is placed in front of the lens-system in some cases and between the lenses in others, and to how many is a Zeiss 'Planar' anything more than a lot of pieces of glass stuck together and mounted in a brass tube. To the optician the book will be invaluable, it being practically the only work on the subject extant. R. W.

Geometrical Optics. By R. A. HERMAN, Fellow of Trinity College, Cambridge. Published at Cambridge by the University Press.

This book covers about the same ground as Heath's well-known work, which it resembles in some respects. The author has adopted a geometrical method instead of the usual analytical method in his treatment of refraction by coaxial surfaces and aberration, and makes use of the reduced path rather than the characteristic function in discussing Maxwell's theorems.

R. W.

DR. GRAY'S FAMILIAR TALKS ON SCIENCE.

A SERIES of little books, entitled 'Nature's Miracles or Familiar Talks on Science' (Fords, Howard and Hurlbut), has been published by Dr. Elisha Gray, and the third volume on 'Electricity and Magnetism' appeared shortly before his death, which occurred in January of the present year. Dr. Gray was unquestionably one of the prominent inventors who contributed his share to the very remarkable progress of electrical science and its application during the past thirty years. The claim often made for him that he was the inventor of the telephone is not justified by the

decisions of the courts. His work in connection with the harmonic telegraph, a very interesting invention which belongs to him, led him to an understanding of the principles underlying the telephone, and the caveat which he filed in the patent office showed that he was very close to the realization of his ideas in this direction. Nevertheless, the fact that Mr. Bell had shown and described an apparatus capable of actually transmitting speech and one which survives to-day as the receiving instrument, gave him a more positive claim which, in connection with other technical and legal facts, resulted in a final decision in his favor. The telautograph, like the harmonic telegraph, has not yet become of great practical value, although both are ingenious and beautiful devices. It would seem that Dr. Gray had been most unfortunate with his inventions in spite of his natural genius. It was not due, however, to lack of mental clearness or grasp, but more likely resulted from insufficient business ability. The books which he has recently written reflect very faithfully the mind of the man. To him science was not abstruse or formal, but a familiar, matter-of-fact and attractive subject. In a clear and picturesque style, he treats the principles and applications of electricity as well as other branches of science. These books could be understood sufficiently to be interesting even by the least technical of readers. On the other hand those well acquainted with the subjects would find at least a new point of view. It is notoriously difficult to write a really satisfactory scientific book of an elementary character. This inherent difficulty is magnified by the fact that most persons who undertake it are not masters of their subject. No such criticism can be made of Dr. Gray, and the lucidity of his ideas and his language are adapted to the task. The writer was well acquainted with Dr. Gray personally and knew his great enthusiasm for science, which is another quality necessary in the writer of an elementary work, in order to inspire his readers who are beginners or those who have comparatively little taste for such matters. For these reasons the series of books that Dr. Gray has written are to be recommended as interesting and instructive to the general or even casual reader, but they are too conversational for use as text-books, except perhaps to supplement other more formal works.

SOCIETIES AND ACADEMIES.

BIOLOGICAL SOCIETY OF WASHINGTON.

The 336th regular meeting was held on Saturday evening, March 9th.

C. W. Stiles presented a note on a recent visit to Texas, whither he had been called to investigate a disease of cattle ascribed to the presence of a parasite in the lungs. He had discovered that the disease was really due to a parasite of the genus *Strongylus* which infested the fourth stomach of the animals infected.

Barton W. Evermann read a paper on 'The Feeding Habits of the Coot and other Water Birds,' based upon observations made at Lake Maxinkuckee, Indiana, by Dr. Evermann and Mr. H. Walton Clark. In 1899 the observations

covered the period from July 1st to October 18th, and in 1900 they began July 1st and have been continued up to date.

Many very interesting observations were made regarding the feeding and other habits of the coot and numerous species of ducks. The paper was devoted chiefly to the coot, the habits of which, at this lake, were found to differ widely from most of the published records of its life history.

It was found that the coot is quite as aquatic in its habits as are most ducks; it swims freely and easily in all parts of the lake. It dives regularly and gracefully when feeding, and in water as deep as twenty-five feet, though its usual feeding grounds were in water four to eighteen feet deep. The longest time any individual was observed to remain under water was sixteen seconds in water ten to twelve feet deep. In deeper water the time was doubtless longer, but could not be definitely determined.

The choice food in September and October was the modified stolons or winter buds of the wild celery (*Vallisneria spiralis*), but later other parts of this plant, and other plants (among them *Myriophyllum verticulatum*, *Potamogeton pectinatus* and other Potamogetons) were utilized. When feeding, which it does at all hours of the day and night, it is not taciturn, as stated by Nuttall, but very sociable and loquacious, constantly talking to its associates day and night; as an article of food the coot is superior to many species of ducks.

Mr. Clark is continuing his observations at Lake Maxinkuckee during the winter and spring, and doubtless other interesting facts will be discovered.

Under the title, 'More about the Cocoanut,' O. F. Cook continued the argument brought forward in a previous paper that the cocoanut palm is an American and not an Asiatic or Malayan species, and that its original habitat is not to be sought on the sea-coast, but in the mountains of Colombia, where it has been reported far inland. It is apparently unable to establish or maintain itself in competition with the usual floras of tropical coasts, and its general dissemination and present range are believed to be the result of human agency. The prehistoric distribution, the Malayo-Polynesian names, and the uses attaching to the cocoanut, the sweet potato and other economic plants of American origin, suggest the probability of a very early westward migration of a primitive culture-race.

A. H. Howell gave some 'Notes on the Distribution and Nomenclature of North American Skunks,' recognizing seventeen species and subspecies and showing specimens illustrating their color variations. Several important changes in nomenclature were referred to, the details of which will be given in a revision of the group about to be published by the Biological Survey of the Department of Agriculture.

F. A. LUCAS.

CHEMICAL SOCIETY OF WASHINGTON.

THE 124th regular meeting was held on February 14th. Dr. H. Carrington Bolton, the retiring president, addressed the Society on the subject 'Physics and Faith.' (SCIENCE, XIII., 320.)

The following papers were then presented: 'The Solubility of Gypsum in Aqueous Solution of Sodium Chlorid,' by F. K. Cameron. This paper was a description of the continuation of investigations along this line previously reported by the author. It was found that the solubility curve presented a maximum point even when calculated on the basis of a given mass of solvent instead of a given volume of solution. A discussion together with the results of experiments was given on the nature of the hydrate of calcium sulfate in the solid phase in contact with certain solutions. A theoretical discussion of the results was presented, and some practical applications pointed out.

'Equilibrium between Carbonates and Bicarbonates in Aqueous Solution,' by F. K. Cameron and L. J. Briggs. The curves showing the distribution of the base between the two salts for solutions in equilibrium with ordinary air were shown. For solutions of the salts of sodium, potassium, or magnesium, as infinite dilution is approached, the bases are all combined as hydrogen carbonates. As the total concentration increases, the percentage of base combined as normal carbonate increases rapidly to a certain point, then asymptotically

and as the solutions approach high concentration, there is again a falling off showing the existence of maximum points on the curves. Solutions of calcium salt contain so little normal carbonate when in equilibrium with air, that practically they may be considered as containing only the hydrogen carbonate. With rise of temperature in all cases, there is an increase in the proportion of normal carbonate in the solution, and at 100° C. all the base is combined as normal carbonate for practically all concentrations. A theoretical discussion accompanied the paper, and practical applications of the results were pointed out.

L. S. Munson,
Secretary.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

The 531st meeting was held March 2, 1901. Under the head of informal communications Mr. Farquhar stated that eye observations on the Nova and Perseus showed considerable fluctuations in brilliancy from night to night. Mr. Bauer stated that the Toronto magnetic observations at the time of the Solar eclipse showed a slight disturbance coincident with the passage of the sun's shadow. Analysis shows that this is due to causes outside the earth's crust, and probably due to changes in the upper atmosphere caused by the passage of the shadow.

The first regular paper was a report by Father Hagen on 'Progress in Astronomical Photometry.' It grouped the facts into four classes:

1. *Photometric Catalogues* with regard to brightness and color of stars. Special mention was made of the Harvard Photometry and of Osthoff's catalogue of star colors.

2. *Original Observations of Variable Stars* were mentioned, in particular those published lately by Peck, Knott and Pickering.

3. The *Physical Explanation* of the light variations is advanced by the discovery of coincidence between the light curves and velocity curves in the three variable stars: δ Cephei, η Aquilae and ζ Geminorum.

4. Various *Charts for Variable Stars*, distributed or published for the convenience of observers, were mentioned, with special reference to Pogson's charts. This part of the report was illustrated by lantern slides.

The next paper was a report by Mr. Radelfinger, on 'Progress in Pure Mathematics in 1900.' This dealt first with important books, referring to the great Mathematical Encyclopedia now in course of publication, and to Forsyth's 'Differential Equations' in two volumes. A brief historical account of the treatment of the ordinary differential equation from the time of Briot and Bouquet introduced an outline of Painlevé's very recent and successful attack on the equation of the second order: he had discovered three new uniform functions, and completely solved the problem of determining all equations of the second order whose integrals are uniform functions. Painlevé's method promises important results from its application to equations of higher orders.

Professor See's report on the 'Progress of Astronomy in 1900' dealt very briefly with the publication of the results of the observations on the Transit of Venus; the observations on Eros, in which about 50 observatories are engaged; the discovery of several hundred double stars, and the publication of double-star catalogues; The observations at the Naval Observatory of planetary diameters with a color-screen; and Rees's new determination of the constant of observation, which he finds to be 20″.464.

Charles K. Wead,
Secretary.

GEOLOGICAL SOCIETY OF WASHINGTON.

At the 111th meeting, held on February 27, 1901, at the Cosmos Club, the following papers were presented:

Memorial of Thomas Benton Brooks: Mr. Bailey Willis. (Published in Science March 22.)

Morphogeny of Southern Alaska: Mr. G. K. Gilbert.

Mountain Structure in the Trans-Pecos Province of Texas: Mr. Robert T. Hill.

The last two papers were illustrated by lantern slides.

F. L. Ransome,
David White,
Secretaries.

SECTION OF GEOLOGY AND MINERALOGY OF THE NEW YORK ACADEMY OF SCIENCES.

AT the meeting of the Section on February 18, 1901, the following program was presented:

'The Granite of Barre, Vermont,' by George I. Finlay. The speaker described the occurrence of the granite as a single intrusion through the country rock, which is a biotite schist, in the southeastern portion of Barre township. Many inclusions of the schist are found in the granite, and this rock has almost surrounded other masses of the schist which remain in place, with their original strike and dip unchanged. The speaker employed a series of original lantern views to illustrate the character of the jointing, the 'onion structure,' and the zones of shearing, together with certain large systems of joints, standing at right angles to each other, resulting from pressure. Microscopic examination shows that the granite consists of microline and orthoclase, plagioclase, in very small amounts, quartz, biotite and muscovite, with occasional crystals of apatite and magnetite and rarely pyrite. Variations in the shade of the marketable granite, from very light to very dark gray, are due to the relative amounts of biotite which it contains. The rock is of medium grain and its constituent minerals are but slightly weathered. Pegmatitic offshoots, traceable directly to the granite mass were recorded by Mr. Finlay, and their dynamic effects on the enclosing schists were illustrated. The contact metamorphism of the schist is inconsiderable. It is chiefly shown in the greater abundance of biotite and quartz in the immediate vicinity of the granite. Two dikes of augite-camptonite were found; one in the granite, the other in the country-rock. They are notable for the manner in which they have weathered. At times sixteen successive shells may be counted which are ready to break away from the main mass of the dike. Mention was also made, in discussing the glacial geology of the region, of sand plains and of two well developed eskers.

The paper was discussed by Professors Kemp and Dodge and Drs. Julien and White.

'Note on a Sand Fulgurite from Poland,' by A. A. Julien. Dr. Julien exhibited a specimen of Fulgurite formed from sand, in Poland, with a series of micro-photographs which he had made from the same. Some new features in fulgurites were pointed out in this specimen: pustules of glass on the inner lumen, glass-fibers on the exterior, and adhering sand-grains, two-thirds of which consist of orthoclase. In the thin cross-section, examination of the minute gas-cavities showed the absence of condensed water-vapor, and this indicated a dilatation of both lumen and cavities by air, more than by steam. The radial arrangement of layer cavities, the hornlike projections on the exterior of the tube, and the pustules along the lumen were all shown to be connected with relief of intense pressure outwardly during the electric discharge, or inwardly during the reaction after its passage. This fulgurite is of further interest in presenting the first instance yet observed of devitrification, the glass being generally filled with delicate crystallites, apparently of feldspar. All the bubbles, however, are enclosed in pellicles of homogeneous glass, and some of the larger within a coating of suddenly chilled glass, which is free from crystallites. The relation of these facts was discussed in reference to Lagorio's view as to the difficult saturation of a magma by the constituents of feldspar.

Other occurrences of fulgurites were discussed by Drs. Kemp, Levison and White.

THEODORE G. WHITE,
Secretary.

THE MINNESOTA ACADEMY OF NATURAL SCIENCES.

THE February meeting of the Academy was addressed by Professor N. H. Winchell and Mr. Warren Upham on the following topics, respectively: 'The Retreat of the Ice Margin Across Minnesota' and 'Giants' Kettles in the Interstate Park, Taylor's Falls.'

Professor Winchell called attention to the general topography by means of a map of the State divided into three areas, viz.: Those areas above 1,400 feet, those between 1,400 and 1,300 feet, and those below 1,300 feet, remarking that, as the ice must have slowly encroached, in the form of glaciers, in the low-
